ACKNOWLEDGEMENT

The EPPSE 3-14 project is a major longitudinal study funded by the Department for Education (DfE). The research would not be possible without the support and co-operation of the six Local Authorities (LAs), and the many pre-school centres, primary schools, secondary schools, and the young people and parents participating in the research.

The views expressed in this report are the authors' and do not necessarily reflect those of the Department for Education

EXECUTIVE SUMMARY	I
SUMMARY OF FINDINGS	II
IMPLICATIONS	X
INTRODUCTION	1
AIMS	2
MULTIPLE IMPUTATION	2
ANALYSES STRATEGY	3
STRUCTURE OF REPORT AND ANALYSES	3
1. CHARACTERISTICS OF THE SAMPLE AT THE END OF YEAR 9	5
1.1. ORIGINAL DATA	6
1.2. IMPUTED DATA	11
1.3. ACADEMIC ASSESSMENTS	13
1.3.1. <i>Descriptive Statistics of Academic Outcomes (Original versus Imputed Data)</i>	14
1.3.2. <i>Associations between Students' Attainment in Different Outcomes and over Time</i>	16
1.3.3. <i>Differences in Attainment for Different Groups of Students</i>	17
Gender	18
Ethnicity	19
Parents' Qualification Level	19
Family Socio-Economic Status (SES) and Free School Meals (FSM)	20
Special Educational Needs (SEN)	22
Early Years Home Learning Environment (HLE)	22
The Key Stage 1 Home Learning Environment (HLE)	23
The Key Stage 2 Home Learning Environment (HLE)	25
Pre-school Attendance	26
2. STUDENTS' ACADEMIC ATTAINMENT AT THE END OF YEAR 9 IN SECONDARY SCHOOL: THE IMPACT OF DIFFERENT INDIVIDUAL STUDENT, FAMILY AND HOME LEARNING ENVIRONMENT (HLE) CHARACTERISTICS	27
2.1. NULL MODELS	28
2.2. INDIVIDUAL MEASURES	30
Age	30
Gender	30
Birth Weight	30
Ethnicity	30
Family Size	31
Early Developmental and Behavioural Problems	31
2.3. FAMILY MEASURES	34
Mother's age	34
Parent's Highest Qualification Level	34
Free School Meals (FSM)	36
Income	36
Family SES	36
Early Years Home Learning Environment (Early Years HLE) Measures	39
Key Stage 1 Home Learning Environment (KS1 HLE)	40
Key Stage 2 Home Learning Environment (KS2 HLE)	41
2.4. NEIGHBOURHOOD 'INFLUENCE'	42
Index of Multiple Deprivation (IMD)	42
Percentage of White British	44
Level of Crime	45
Income Deprivation Affecting Children Index	46
Neighbourhood Safety	47

3. STUDENTS' ACADEMIC ATTAINMENT AT THE END OF YEAR 9 IN SECONDARY SCHOOL: THE IMPACT OF PRE-SCHOOL, PRIMARY AND SECONDARY SCHOOL	49
3.1. THE IMPACT OF PRE-SCHOOL EXPERIENCE ON YEAR 9 ATTAINMENT	50
3.1.1. <i>The Continuing Impact of Pre-School Attendance at Later KS3 Attainment</i>	51
3.1.2. <i>The Continuing Impact of Pre-school Centre Quality at Later KS3 Attainment</i>	51
3.1.3. <i>The Continuing Impact of Pre-school Centre Effectiveness at Later KS3 Attainment</i>	52
3.1.4. <i>Different Pre-school Effects for Different Groups of Students</i>	54
The Combined Impact of Pre-school Experience and Early Years Home Learning Environment (HLE)	54
Early Years HLE and Pre-school Attendance	54
Early Years HLE and the Quality of the Pre-school	58
Early Years HLE and Pre-school Effectiveness	62
Parents' Qualification Level and the Impact of Pre-school Experience	66
Parents' Qualification Level and Pre-school Quality and Effectiveness	69
3.2. THE IMPACT OF PRIMARY SCHOOL ACADEMIC EFFECTIVENESS ON YEAR 9 ATTAINMENT	77
Influences of Primary School Academic Effectiveness for Different Groups of Students	80
Parents' Qualification Level and the Impact of Primary School Academic Effectiveness	80
The Combined Impact of Pre-School Experience and Primary School Academic Effectiveness	83
The Combined Impact of Pre-School Effectiveness and Primary School Academic Effectiveness	87
3.3. THE IMPACT OF SECONDARY SCHOOL ON YEAR 9 ATTAINMENT	90
3.3.1. <i>The Impact of Secondary School Academic Effectiveness on Year 9 Attainment</i>	91
3.3.2. <i>The Impact of Secondary School Quality on Year 9 Attainment</i>	91
The Impact of the Quality of Pupils' Learning and Their Progress on Year 9 Attainment	92
The Impact of the Learners' Attendance on Year 9 Attainment	93
3.3.3. <i>The Combined Impact of Pre-School Experience and Secondary School Academic Effectiveness</i>	94
3.4. SUMMARY OF PRE-, PRIMARY AND SECONDARY SCHOOL INFLUENCES	95
4. EXPLORING THE EFFECTS OF SCHOOL, TEACHING PROCESSES AND STUDENTS' VIEWS OF THEMSELVES ON LATER KS3 ATTAINMENT	96
4.1. TEACHING AND SCHOOL PROCESSES	96
4.1.1. <i>Emphasis on Learning</i>	97
4.1.2. <i>Behaviour Climate</i>	98
4.1.3. <i>School Environment</i>	99
4.1.4. <i>Valuing Pupils</i>	99
4.1.5. <i>School/Learning Resources</i>	100
4.1.6. <i>Emphasis on Learning and Behaviour Climate</i>	101
4.2. TIME SPENT ON HOMEWORK	102
4.3. STUDENTS' VIEWS OF THEMSELVES	103
4.3.1. <i>Maths and English Academic Self-Concepts</i>	104
4.3.2. <i>Enjoyment of School</i>	106
4.3.3. <i>Anxiety Behaviours</i>	107
5. EXPLORING RELATIVE ACADEMIC PROGRESS BETWEEN YEAR 6 AND YEAR 9	108
5.1. THE IMPACT OF INDIVIDUAL STUDENT, FAMILY AND HOME LEARNING ENVIRONMENT (HLE) CHARACTERISTICS	110
5.2. THE IMPACT OF PRE-, PRIMARY AND SECONDARY SCHOOL EXPERIENCE	117
5.2.1. <i>The Impact of Secondary School Academic Effectiveness</i>	117
5.2.2. <i>The Impact of Secondary School Quality</i>	117
The Impact of the Quality of Pupils' Learning on Academic Progress in Secondary School	118
The Impact of the Learners' Attendance on Academic Progress in Secondary School	119
5.3. EXPLORING THE EFFECTS OF SCHOOL AND TEACHING PROCESSES ON ACADEMIC PROGRESS DURING KS3	121
5.3.1. <i>Time Spent on Homework</i>	127

6. DOES THE PRIMARY TO SECONDARY TRANSITION AFFECT KS3 OUTCOMES?	129
7. THE IMPACT OF PRIMARY SCHOOL MOBILITY DURING KS1 AND KS2	134
7.1. THE IMPACT OF COMBINED TERMS OF MOBILITY AND FSM ON KS3 OUTCOMES	142
8. SUMMARY AND CONCLUSIONS	143

Executive Summary

The Effective Pre-School, Primary and Secondary Education (EPPSE 3-14) project represents the secondary school phase of a major longitudinal study that had started in 1997. The original first phase of the research, the Effective Provision of Pre-school Education (EPPE1997-2003) project, was designed to explore the impact of pre-school on children's cognitive and social-behavioural outcomes, as well as other important background factors (family and home learning environment). For this purpose, a pre-school sample was recruited to the study at age 3 years. Subsequently, this project was extended and the same sample was followed through primary school from age of seven to age eleven - Key Stage 1 (KS1, Year 2) and Key Stage 2 (KS2, Year 6). An additional 'home' sample of children (who had not attended pre-school) was recruited at the start of primary school and was followed similarly with the pre-school sample up to age fourteen. The EPPSE 3-14 project is an extension of this initial research and follows the same sample (pre-school and 'home' children) during KS3 of secondary schooling (to the end of Year 9) at age 14 years plus.

The research design of this project has been based on an educational effectiveness and mixed methods approach (Sammons et al., 2005; Siraj-Blatchford et al., 2006). This type of design allows for the study of individual, family and home influences on academic and developmental outcomes. Furthermore, the relative importance of specific background influences can be investigated in relation to the strength of pre-school, primary and secondary school factors.

The report presents the results of analyses related to the influence of pre-school, primary and secondary school on students' academic attainments at the end of Year 9 when the young adults were aged fourteen, and their academic progress from the age of 11 to age 14 during KS3. The findings also extend and develop the findings from previous earlier ages. A report on students' social-behavioural development throughout the same period will be presented separately (Sammons et al., 2011a).

Throughout its research, EPPSE 3-14 has gathered a wide range of data on children's development, individual, family, home learning environment (HLE), pre-school and primary school characteristics. Additional measures of secondary school's academic effectiveness¹ derived from KS2-KS4 contextual value added (CVA) indicators produced by the DfE have been added to the EPPSE data set. Also, various Ofsted inspection judgements were used to provide independent indicators of the quality of secondary schools. These were used to complement the measures of quality² and effectiveness³ for pre-school settings and the measures of primary school effectiveness⁴. It was therefore possible to explore pre-school, primary and secondary school influences on students' outcomes in Year 9.

¹ Independent indicators of secondary school academic effectiveness and quality were obtained from the Department for Education. The measure of academic effectiveness is represented by the average KS2 to KS4 contextual value added (CVA) school level score over 4 years (2006-2009) during which the EPPSE students were in secondary school. However, DfE no longer uses this approach. A value added measure is used instead which measures progress, but does not take background into account. The measure of secondary school quality was derived from various Ofsted inspection judgments.

² Pre-school quality was measured for each pre-school centre using the aggregate score from the ECERS-E (see Glossary) across scores for the curricular activities of Literacy, Numeracy, and Science/knowledge of the world, and on Diversity of provision for children of different abilities, gender and cultures (Sylva et al., 1999).

³ Measures of the effectiveness of individual pre-school centres were derived from value added models of the EPPE 3-11 children's actual progress during the pre-school period, controlling for prior attainment and children's background characteristics (Sammons et al., 2004a). That is, children's cognitive progress was analysed from age 3 to rising 5 years.

⁴ Independent indicators of primary school academic effectiveness were obtained from the analysis of National Assessment data for several cohorts across all primary schools in England. Mean value added scores of school academic effectiveness across the years 2002 to 2004 were calculated for each primary school in England and then extracted for schools attended by children in the EPPE 3-11 sample. These

National curriculum levels awarded for Teacher Assessment (TA) in English, maths and science have been used to provide measures of students' educational outcomes in Year 9 and standardised scores of National Assessments in English and maths in Year 6 have been used as measures of prior attainment. The sample included 3002 students for whom we had at least three cognitive assessments from age 3 to age 14.

The aims of the research were to:

- Investigate the relationships between students' academic attainment in KS3 (Year 9, age 14) and background individual, family and home learning environment (HLE) characteristics.
- Explore the influence of pre-school, primary and secondary school experiences, particularly in terms of quality and academic effectiveness on later academic outcomes and academic progress.
- Examine the combined impact of pre-school characteristics with the (HLE) and primary school experience on academic attainment.
- Assess whether the impact of pre- and primary school differs for more and less disadvantaged children.
- Investigate the combined effect of secondary school experience with pre- and primary school experiences on academic attainment.
- Model students' current academic *attainment* in Year 9, and their *progress* over KS3.
- Explore the effects of teaching, school processes and students self-perceptions on academic attainment.

Summary of Findings

This report provides a detailed investigation of the academic attainments of the EPPSE sample of students at the end of KS3. It builds on earlier research that has followed this group from early childhood at age 3 years through primary school and into secondary school up to age 14.

Previously the project has demonstrated that a range of factors related to child and family characteristics and the home learning environment are important predictors of children's academic attainments and progress up to the end of primary school (Sammons et al., 2008a; Sylva et al., 2010). The impact of these influences can be detected from a young age and can also affect later educational attainment. The variations in achievement point to the negative effects of socio-economic disadvantage and the results of the research have contributed to policy developments in England associated with issues of equity and social inclusion (see The Equalities Review, 2007).

This current follow up of the sample in adolescence (Year 9 age 14) provides new evidence about the size of the equity gap in attainment as measured by teachers' judgements of student attainment in the three 'core' curriculum areas of English, maths and science (reflected by differences in TA levels).

In contrast to earlier research on this sample (during KS2), it was not possible to study variations in students' KS3 attainment using national assessment test scores as outcomes, due to a change in education policy. Instead, the analyses presented in this report are based on TA judgements that are less finely differentiated than test scores and tend to reflect greater subjective bias due to possible 'halo effects' (see Bew, 2011; Harlen, 2004). However, teacher judgements of attainment in Year 9 is likely to play an important role in shaping students' future educational decisions and subject choices in KS4 and therefore, can be viewed as important measures of educational outcomes to investigate.

The analyses in this report identify which child, family and home learning factors predict EPPSE students' KS3 outcomes. The results show similarities to earlier findings for this sample. A brief summary of the main findings is presented. While many results on the impact of gender, parents' qualifications or SES are in accord with those from other educational research studies, EPPSE also reveals the continued importance of the early years Home Learning Environment (HLE). The EPPSE project is unique in its exploration of the influence of this factor across different phases of students' education and has identified the way that the early years HLE continues to predict attainment up to age 14. In addition, the latest research discussed in this report demonstrates that various family background factors continue to influence students' academic progress across KS3. It should be noted that in the progress analyses, prior attainment in national assessment tests taken at the end of primary education (Year 6, KS2) was used included as a baseline in the statistical models.

This report focuses on statistical trends and quantitative analyses of factors that predict attainment and progress in KS3 based on results using multilevel statistical models. Elsewhere, EPPSE has reported (in keeping with the mixed methods research design involving both quantitative and qualitative approaches) findings from qualitative case studies of children and families that are more educationally successful in overcoming disadvantage (see Siraj-Blatchford et al., 2011). The qualitative data helps to provide a broader understanding of the way social disadvantage shapes students' educational outcomes and experiences at different ages and what factors help to protect against the adverse consequences of disadvantage.

As well as investigating the impact of child, family and HLE background, the EPPSE research has explored the continued influence of pre-school and primary school as predictors of students' later attainment at age 14 and also tested a range of measures related to secondary school experiences. The results, therefore, provide new evidence on the way different educational settings (pre-school, primary and secondary school) affect attainment and progress in KS3.

In order to maximise the sample size in our analyses, multiple imputation of missing data was used. Careful comparison of the results from both imputed and non imputed data sets were conducted and indicate that the results are robust producing very similar and the patterns consistent.

Raw Differences in Attainment for Different Student Groups

Overall, EPPSE students' had higher average attainments in maths than in either science or English (a difference of around 0.5 of a national curriculum level comparing maths and English, and 0.36 of a level comparing maths and science) at the end of KS3. This pattern of higher results in maths is in line with the most recent international TIMSS survey (Martin et al., 2008; Mullis et al., 2008; Sturman et al., 2008) of maths and science achievement that revealed England as the highest performing country in Europe in maths with the most improved results since 1995. It is likely that this improvement is linked with the introduction of the National Numeracy Strategy in 1998 (DfEE, 1998). In interpreting the KS3 results, it should be noted that EPPSE students had experienced the numeracy strategy in their primary education.

Gender

In Year 9, girls had higher attainment in terms of average TA English results than boys by around 0.4 of a national curriculum level (approximately half a standard deviation in size), but there were no significant gender differences in maths or science results. At younger ages, girls had been shown to have higher attainment in Reading and English and there were also smaller differences in maths and science outcomes in primary school but by age 14 these differences have disappeared.

Ethnicity

There was some evidence of ethnic differences in attainment but due to low numbers for most groups in the EPPSE sample the results should be interpreted with caution. Nonetheless, the differences found in average results by ethnic group are in line with those evident in other studies

indicating higher attainment for some groups e.g. Indian and lower for others e.g. those from Pakistani heritage.

Family Characteristics

There were marked differences in attainment related to parents' qualification levels. As might be anticipated, students with highly qualified parents (degree level) had much higher attainment on average than those students whose parents had no qualification (the difference was equivalent to 1.4 TA levels for English, 1.7 for maths and 1.5 for science).

There were similarly large differences related to family socio-economic status (SES) between those from professional non-manual and those from lower SES categories. Moreover, students eligible for Free School Meals (FSM) had lower average attainment than students who were not eligible for FSM. The differences were around 0.7 and 0.8 of a national curriculum level in each subject.

Differences in the Early Years HLE were also associated with later differences in average attainment Year 9. The difference for English and science was approximately 1 national curriculum level, for maths it was 1.3 of a level for those of high versus low scores.

The Net Impact of Child, Family and HLE Factors on Attainment in Year 9

The average group differences described above do not take into account the relative influence of other characteristics. Multilevel modelling provides more detailed results of the 'net' contribution of individual factors, whilst controlling for other predictors and so enables the identification of the 'strongest' net predictors. For instance, we show the higher attainment in students with mothers who have degrees compared to those with no qualifications, net of the influence of other family and child factors (SES, income, HLE or gender).

Mother's qualification level was the strongest predictor of better attainment for English, maths and science. The next strongest predictor was gender but for English only, where the effect was larger in KS3 than was the case when these students were in primary school.

There were also a number of additional strong/moderately strong predictors as follows for:

English: family income, birth weight, father's highest qualification level, and the Early Years HLE;

Maths: birth weight, Early Years HLE, father's qualification level, ethnicity and family SES;

Science: father's qualification level, Early Years HLE, family SES and ethnicity.

It should be noted that ethnicity was not a significant predictor of TA levels in English, but it was for maths and science; students of Indian heritage obtained significantly better results in maths and science than White British students. Both FSM (the low income indicator) and family SES also have moderate effects on English, maths and science. These effects were similar in size to the effects of the Early Years and KS1 HLE for English. The Early Years HLE had a stronger impact on students' KS3 maths and science attainment than the low income indicator FSM.

Older students (for their age group e.g. Autumn born) also showed better results though the effect was not strong. There were also small positive effects related to the age of the child's mother (at birth); the older the mother then the better the outcomes, compared to children of younger mothers.

There is evidence that the 'social composition' of the school (as measured by the percentage of students entitled to free school meals, an indicator of poverty) can affect individual student's outcomes over and above their own FSM status. EPPSE students who attended a secondary school with higher proportions of students receiving FSM showed poorer attainment in English, maths and science, although the effects were relatively weak.

These results broadly confirm patterns identified at younger ages indicating that differences in attainment related to individual student and family background influences emerge early (at age 3) and remain fairly stable as students progress through primary and secondary school. The results supporting this conclusion are well established in previous social and educational research.

Neighbourhood Influences

A number of neighbourhood measures were tested as potential predictors of students' KS3 academic attainments. Previous research has suggested that contextual influences outside the family (such as school and neighbourhood composition) may influence student attainment. Living in a disadvantaged area and attending a school with a higher representation of disadvantaged students, may affect student and family aspirations and attitudes to education and also teacher expectations.

The DfE's national Contextual Value Added (CVA) measure of school performance has demonstrated that the school measure (percentage of FSM students) and neighbourhood measures such as the IMD and IDACI score predict student progress. As noted above the percentage of students on FSM in a secondary school also predicted attainment for the EPPSE sample.

Levels of neighbourhood disadvantage (measured by the IMD - Noble et al., 2004; and IDACI - Noble et al., 2008) were also significant predictors of lower student attainment in English and science in Year 9. This was not the case during the primary school years, possibly because neighbourhood influences increase as adolescents interact more with their peer group outside the home. Students who live in disadvantaged neighbourhoods had poorer attainment, over and above their own and their family characteristics, although these neighbourhood effects are relatively small compared to those of the family.

Other neighbourhood measures were also obtained by the EPPSE research. These included the level of employment and the percentage of residents with limiting long term illnesses, but neither of these was found to predict students' attainment. In contrast, the percentage of the population who were classed as White British was statistically significant with small negative effects for each subject. The level of crime recorded in a neighbourhood was also found to have small negative effects on attainment and progress in English and science. Similarly, parents' perceptions of the safety of their neighbourhood also showed small positive effects on attainment (maths and science) and progress (science).

Taken together the results indicate attainment was lower for students who lived in more disadvantaged neighbourhoods compared to those in more advantaged neighbourhoods, over and above their own and their family characteristics. The neighbourhood influence though relatively small seems to have become stronger in as the EPPSE sample go through early adolescence.

Pre-school

The EPPSE research was designed to follow up children recruited at pre-school into primary and later secondary school in order to identify and investigate the contribution of different educational influences on their later progress and development in different phases of education. In addition to investigating individual student, family, home learning and neighbourhood, further analyses sought to establish whether pre-school influences identified as significant predictors of attainment and progress in both cognitive and social-behavioural outcomes at younger ages still show effects nine years later when the variation in attainment is studied up to age 14 years.

Three measures were tested: whether or not the student had **attended** a pre-school (a comparison with the 'home' group); the **quality** of the pre-school attended (as measured by the ECERS-R and ECERS-E environmental rating scale instruments) and the **effectiveness** of the pre-school attended.

Attendance

Just having attended a pre-school was found to be a statistically significant predictor of better attainment in both maths and science (but not English) at the end of KS3, compared with the 'home' group. Although relatively weak ($ES=0.26$ for maths and $ES=0.22$ for science), these effects were still stronger than those found for 'age' (being Autumn born) and similar to the effect for family income (in both maths and science).

Quality

The quality of pre-school also continued to predict better outcomes in maths and science nine years after leaving pre-school. The effects of medium and high quality were slightly larger than for low quality (compared to 'home' group). For example, the ES for high quality was 0.28 for maths. In science, only those who had attended a medium or high quality pre-school continued to show significantly better attainment than the home group in TA levels at age 14.

Effectiveness

The indicator of pre-school effectiveness in promoting pre-reading skills continued to predict better outcomes in English in lower secondary school. However, only the highly effective category was statistically significant ($ES=0.20$) in predicting better attainment when compared to the 'home' group.

For maths, all groups ($ES=0.36$ for high; $ES=0.22$ for medium; and $ES=0.30$ for low effectiveness) had significantly better results than the 'home' group after controlling for other factors. For science, attending a high ($ES=0.33$) or medium effective ($ES=0.19$) pre-school (in promoting early number concepts) predicted significantly better outcomes than not attending a pre-school. Those attending a low effective pre-school showed no better outcomes in science by the end of KS3 than the 'home' group.

Primary School Influence

Previous EPPSE research has shown that the academic effectiveness of a child's primary school is a statistically significant predictor of better attainment and progress across KS2 for English and more strongly for maths. Other educational effectiveness research has shown that primary schools can continue to influence students' longer term academic outcomes at secondary school (Goldstein & Sammons, 1997; Leckie, 2009). Measures of the academic effectiveness² in English and maths of the primary school attended by the EPPSE students were explored to see whether they had a positive influence on later attainment at the end of KS3. The KS3 analyses reveal that the academic effectiveness of the primary school the EPPSE students had attended still predicted better outcomes for both maths and science attainment three years after transferring to secondary school.

Controlling for student, family and HLE background characteristics, by the end of KS3, the extra benefit of attending a medium effective primary school was relatively small compared with the low effective group ($ES=0.13$ for maths). The net effects of attending a high academic effective primary school on later attainment compared with the effects of attending a low effective one were rather stronger ($ES=0.31$ for maths & 0.29 for science). The effects are similar in size to those attributable to FSM. The effect in terms of TA levels is a third of a level for maths and a quarter of a level for science.

Combined effects of phases of education

Pre-school and HLE

Further analyses also explored joint effects of pre-school and the Early Years HLE. The results showed that those with a low Early Years HLE obtained better outcomes in terms of later English, maths and science if they had attended a pre-school. The net differences were equivalent to between 0.4 and 0.7 of a national curriculum level ($ES=0.37$ for English; $ES=0.56$ for maths and $ES=0.48$ for science).

The quality of the pre-school measured by ECERS-E no longer showed differences in relation to students' Early Years HLE for English, maths or science in Year 9, in contrast to findings from the primary school.

There was an indication that the effectiveness of the pre-school in promoting early number concepts mattered in the study of joint effects for later science in Year 9. Here for both the low and the high HLE group there was evidence of a trend. Those with a low Early Years HLE showed particular benefits if they had previously attended a high effective pre-school ($ES=0.61$) showing similar results in terms of boost to those who had a medium or high HLE who had not attended pre-school.

These results again suggest that high effective pre-school experience may have some compensatory benefits in promoting better later academic outcomes in science up to age 14.

Primary-school effectiveness and parent's qualification level

Further analyses explored joint effects for different student groups. For students whose parents had low educational qualifications, the boost in maths predicted from attending a high effective primary school compared with a low effective one was also larger (difference in ES=0.33) than the boost provided for students of parents with higher qualification levels (difference in ES=0.17). A similar pattern of results was found for science Year 9 TA levels. This suggests some continuing compensatory impact of previous attendance of a more academically effective primary school for students whose parents have lower educational qualifications.

Primary school and pre-school

The joint effects of pre-school quality and the primary school effectiveness were also investigated. These also pointed to the continued benefits of primary school academic effectiveness even when pre-school effects are taken into account for both maths and science outcomes in Year 9.

Pre-school effectiveness (in promoting early number concepts) was tested jointly with the primary school academic effectiveness measure and the results indicated that attending a high effective pre-school offered some protective effects (even if a student went on to a less effective primary school) for later maths and science outcomes. Likewise, having attended a more academically effective primary school mitigated the effects of experiencing no or only a low effective pre-school. The longer term protective effects of pre-school effectiveness were shown most clearly for students who then attended a low academically effective primary school when we studied their later attainment in Year 9 of secondary school.

Secondary and pre-school effectiveness

Further analyses of the combined effects showed that the continued benefits of pre-school were most evident for EPPSE students who went on to attend medium or low effective secondary schools, suggesting a protective influence of pre-school against attending an ineffective secondary school.

Transition from Primary to Secondary School

A subsample of approximately 550 EPPSE students and parents were asked about their personal experiences and views related to the transition from primary to secondary school, including their settling down in the new school, the academic work, their friendships and things that primary/secondary schools did to assist or smooth the transition. Five factors were identified to be deemed salient in the transition (Evangelou et al., 2008 for full details):

- Developing friendship, self-esteem and confidence
- Settling into school life
- Showing interest in school and schoolwork
- Getting used to new routines
- Experiencing curriculum continuity

EPPSE examined the importance of the transition experience on subsequent achievement and found that, those students who settled quickly into school routines and who experienced continuity in the curriculum from primary to secondary school made better progress in maths and science across KS3 and also had higher attainment in all three core subjects at Year 9. Although statistically significant, these effects were relatively small (ES range between 0.21 and 0.32). Other transition factors were less predictive of school-success, suggesting that familiarity with the school building and routines, along with familiar curriculum materials in lessons were more important during transition than the psychological dimensions of self-esteem and confidence or the social dimension of settling into school (social) life.

Primary School Mobility

The present report also explored the relationships between mobility during KS1 and KS2 in primary school and students' later academic outcomes in KS3. Results showed that mobility during KS2 was a negative predictor of Year 9 TA levels in English, maths and science. Students who had changed primary school only during KS2 obtained lower levels of Year 9 TA in all three core areas of the curriculum English, maths and science, even when the analyses controlled for the influence of a range of student and family background characteristics, HLE, neighbourhood disadvantage and school level FSM. Additionally, for maths, mobility during KS1 was also found to be a negative predictor of lower levels of TA in Year 9. Students who had moved primary schools during KS1 obtained significantly lower levels of TA in maths in Year 9 than students who had not moved at all.

Overall, these analyses of EPPSE students' attainment in English, maths and science in Year 9 has provided a wide range of evidence concerning the factors that predict attainment in Year 9 as measured by TAs, and also progress across KS3.

Secondary School Influences

We tested the academic effectiveness of secondary schools using CVA measures derived from the DfE's National Pupil Database. These measures show the relative progress made by student intakes measured from KS2 to KS4 (across 5 years). In contrast to our primary school academic effectiveness measure that examined results in English, maths and science separately (Melhuish et al., 2006a; 2006b), we did not have subject specific results for these secondary school CVA indicators. The secondary school CVA measure of effectiveness did not predict EPSSE students' differences in attainment in Year 9, after controlling for individual student, family and HLE measures.

However, after controlling for the same characteristics, the quality of secondary school measured by Ofsted inspection ratings on the 'quality of students' learning' was a statistically significant predictor of attainment in both English and science, with the difference being only statistically significant (but moderately strong) for the 'outstanding' schools category compared with the 'inadequate' category (ES= 0.42 English, ES=0.51 science).

For maths, schools judged by Ofsted as 'good' (on quality of learning) showed more modest but significant positive effects (ES=0.26) and those judged as 'outstanding' showed stronger effects (ES=0.56) compared with the 'inadequate' category.

These results support the hypothesis that secondary school quality remains important in shaping students' academic attainment, over and above the impact of background factors. The effects are equivalent to between 0.34 and 0.64 of a TA level for those who attended an 'outstanding' rather than an 'inadequate' school (in terms of the Ofsted judgement 'quality of learning'). A similar strong pattern was identified for Ofsted judgements of learners' attendance. It should be noted that these two Ofsted measures (quality of learning and learners attendance) are also correlated.

Students' Progress across Key Stage 3

Students' academic progress across KS3 was studied by controlling for the prior attainment at the end of primary school and taking account of individual student, family and HLE factors. Fewer background factors predicted progress across KS3 than were significant for attainment. The patterns were similar to those found to be at younger ages when we studied students' progress across KS2 for this sample.

Overall, there was evidence that students:

- older for their year group (Autumn born) (ES=0.24-English, ES=0.32-maths and ES=0.20-science),
- girls (ES=0.32-English, ES=0.16-maths and ES=0.17-science),
- with highly qualified fathers (ES=0.28-English, ES=0.28-maths and ES=0.43-science), made more progress in English, maths and science over KS3.

Students whose mothers were highly qualified (degree/higher degree) made better progress in English (ES=0.34) and science (ES=0.33). Additionally, students whose families had high incomes also made better progress in English (ES=0.39). There were small negative effects related to early behavioural problems, and eligibility for FSM.

A higher percentage of students in a school eligible for FSM predicted poorer progress for the EPPSE sample in both English (ES=0.18) and science (ES=0.21). Of the neighbourhood measures tested, only the percentage of White British and the level of reported crime were significant predictors of poorer student progress in English. For progress in science however, reported crime, perceived neighbour safety, the IMD and IDACI were statistically significant predictors. These findings indicate that the disadvantage of the school's intake and students' neighbourhood characteristics had small negative effects predicting both poorer progress and attainment and shows that schools in some areas face more challenging circumstances in improving student learning outcomes.

Neither the pre-school measures nor the primary school academic effectiveness measure were significant predictors of students' progress in KS3. However, the secondary school overall academic effectiveness indicator was found to be a statistically significant predictor for progress in English.

Higher Ofsted measures of the 'quality of students' learning' and 'attendance of learners' also proved to be significant predictors of better progress in all three core subjects. EPPSE students who attended an 'outstanding' secondary school in terms of the 'quality of learning' made significantly more progress in the three core subjects than those in schools judged to be 'inadequate' (ES ranged between 0.29 and 0.36). Additionally, students from secondary schools characterised as 'outstanding', 'good' or even 'satisfactory' in terms of 'students' attendance' made significantly more progress in English (ES=0.48 for outstanding) and maths (ES=0.35 for outstanding). These findings provide some evidence of external validity for the use of Ofsted inspection judgements and are in line with earlier results on a sub-set of primary schools investigated as part of the EPPE 3-11 phase of the research (Sammons et al., 2008c).

Students' experiences and views of secondary school

Students' secondary school experiences were measured using self-report questionnaires administered in Year 9. Various measures of school experiences were identified and tested to see if they predicted variations in students' KS3 academic attainment and progress after control for individual, family and HLE factors, including the percentage of students on FSM in the school.

The results indicate that students who perceived their school to place higher 'emphasis on learning' had significantly higher attainment. The difference was between half in English and science to three quarters of a TA level for maths (ES ranged between 0.20 and 0.22).

EPPSE students' attainment was also found to be higher where they perceived a more 'positive behaviour climate' in their secondary school. The difference was particularly noticeable for maths (ES=0.46). The perceived quality of their 'school environment'⁵ was also a predictor of better attainment, although the effects were smaller and only significant for maths and science (ES=0.13 for both). Similar, small but positive effects were identified for the factor related to students' perceptions of how much they felt teachers' valued and respected them. Finally, the factor 'learning resources' (related to whether students felt the school was well equipped with computers and technology) also predicted better attainment in maths (ES=0.13) and science (ES=0.15) in KS3. Although the effect sizes are relatively small, this is the equivalent of around half a TA level for both these subjects.

⁵ This factor includes attractive and well decorated buildings, cleanliness of toilets etc.

After testing these factors separately as predictors of attainment, we also tested them together to investigate which ones are the most important in predicting academic outcomes in Year 9 when still controlling for individual student, familial and HLE characteristics. . For all three core curriculum subjects, it was found that the two factors 'emphasis on learning' and 'behaviour climate' together significantly predicted Year 9 academic attainment.

Looking only at students' progress during KS3 'behaviour climate', 'valuing pupils' and 'teacher support' were significant predictors of progress in English, maths and science. 'School environment and 'learning resources' were only significant for maths and science. 'Headteacher qualities' was a significant predictor for progress in maths (ES=0.15). Finally, 'teacher behaviour management' was a significant predictor of progress in science (ES=0.14).

After control for individual, family and HLE influences, the daily time spent on homework, as reported by students, was found to be an important and strong predictor of better attainment and progress. The strongest effects were noted for those who reported 2-3 hours per day. For attainment in English this had an ES of 0.73 (equivalent to 0.6 of a TA level). For attainment in maths, the ES was 0.84 (equivalent to almost 1 TA level) similar to the effects for science (ES 0.85, equivalent to nearly 0.75 of a level). For academic progress in the three core subjects, the ES for 2-3 hours of homework/day ranged between 0.69 and 0.84. Spending more time on homework is likely to increase study skills and opportunities to learn, it may also be influenced by self-regulation. It is also likely to reflect secondary school policies and teacher expectations and the academic emphasis in the school as well as encouragement from parents to take school work seriously.

Students' views of themselves

Earlier EPPSE research (Sammons et al., 2008d) has shown positive relationships exist between academic self-concept and attainment. Higher academic self-concept predicts better attainment and vice versa. Patterns of attainment and self-concept in younger children can shape their future identities as learners. The results for EPPSE students in secondary school show fairly strong links between academic self-concept in maths as a predictor of attainment in Year 9 (ES=1.2; nearly 1 TA level). By contrast, academic self-concept in English was a weaker predictor of Year 9 English attainment (ES=0.74; equivalent to approximately a half of a TA level). Students' self-reported enjoyment of school, also predicted attainment, with stronger effects for maths (ES=0.38 maths; ES=0.31 science; ES=0.29 English).

Implications

The socio-economic characteristics of the individual student's family continue to influence academic attainment at the end of KS3 in the three core curriculum areas. This research also provides evidence that the school and neighbourhood in which students are positioned, can also affect outcomes. The early years HLE remains an important predictor of better attainment at age 14 and this has relevance for the development of policy regarding families and parenting. The research has implications for the debate on the drivers of social inequality and has messages for both policy and practice that may help to narrow the gap in educational outcomes and improve children's and young people's learning over their life course.

In addition, the specific characteristics of educational institutions predict attainment up to the end of KS3. Firstly, the child's experiences within a pre-school centre continue to predict attainment through primary and into secondary school. There are continuing effects of pre-school attendance and also of pre-school quality and effectiveness, particularly for later attainment in maths and science. This is relevant to the development of policies which increase the quality and effectiveness of pre-school and is especially important given the increased numbers of children who now take up their funded place.

The findings also provide evidence that the academic effectiveness of their primary school not only influences EPPSE students' attainment and progress during KS2, but also continues to predict better outcomes in maths and science later on in KS3. This shows the relevance of educational effectiveness (CVA) indicators (of primary school performance in specific subjects) for both policy

makers and practitioners in providing useful information to help evaluate institutions. Other research has also demonstrated that more effective schools tend to make greater use of performance data to help improve their practice (Day et al., 2009).

There is also evidence of secondary school effects on students' progress across KS3. The Ofsted inspection indicator of school 'quality' predicts both attainment and progress over and above individual, family, HLE and neighbourhood characteristics. Attending a school judged to be 'outstanding' by Ofsted provides a moderately large boost to student attainment outcomes in all three core areas of the curriculum.

Moreover, the results point to the importance of the students' own perceptions and their views. Students' views of some school processes predicted differences in attainment and progress. Focussing on improving areas of the secondary school experience such as 'emphasis on learning' and the school's 'behaviour climate' for all three core subjects plus good 'learning resources' (for maths and science) is likely to promote better academic results and improved social-behavioural development (Sammons et al., 2011a; 2011b show these factors predict better social-behavioural outcomes and dispositions⁶). This suggests that consulting students and obtaining their views is likely to be extremely helpful for school self-evaluation.

These results indicate that optimising each phase of education, pre-, primary and secondary school has the potential to improve the attainment of the whole school population in the longer term. These findings build on and extend findings reported for the EPPSE students at younger ages and show that better pre-schools and primary schools continue to have a protective effect in terms of boosting later attainment for all students.

Parenting is important too, and improving the early Years home learning environment (HLE) is likely to benefit the educational attainment of children in both the short term and the whole population in the longer term since such effects are shown to last into adolescence. All of these points are particularly relevant for young people growing up in disadvantaged families and neighbourhood contexts.

By 2050, the working age population within Europe will decrease by approximately 12 per cent, whereas the elderly will increase by 50 per cent. In these circumstances, maximising the productivity of the working population is necessary for economic sustainability. One strategy to increase productivity is to enhance educational attainment across the population. This is especially important when the skills necessary for modern economies are rising and changing in nature and when there is still great inequality of opportunity and outcomes. The results of this study provide some pointers to strategies that may help to address these issues in the medium to longer term.

⁶ 'Dispositions' here refer to factors such as academic self-concepts, enjoyment of school and citizenship values etc.

Introduction

EPPSE 3-14 is a large-scale, longitudinal study funded by the Department for Education (DfE), originally designed to investigate the types of early childhood provision that are the most 'effective' in promoting young children's development during pre-school. This project was then continued and followed the EPPE sample into primary and later into secondary school. The aims were to explore whether any pre-school effects persist later in primary and secondary school, but also to examine primary and secondary school influences on development and outcomes.

Initially the project tracked children from pre-school, or, for the home group, at the start of primary school, to the end of Key Stage 1 (KS1) of primary school (age 7 plus years). Measures of the quality of 141 pre-school centres were recorded from five regions across England. The centres were representative of six types of provision: nursery classes, playgroups, local authority day nurseries, private day nurseries, nursery schools and integrated centres [i.e. combined centres that integrate education and care] (see Sammons et al., 2002; 2003). Results of analyses of children's outcomes in KS1 were reported by Sammons et al., 2004b and 2004c.

An extension to the original EPPE pre-school study has tracked the same children's development to the end of KS2 (age 11) (Sammons et al., 2007a; 2007b; 2008a; 2008b⁷; Sylva et al., 2010). This second phase was designed to explore continuing pre-school influences as well as to investigate the effects of primary school. EPPE 3-11 was the first study of pre-schools in Europe to adopt an educational effectiveness design based on sampling children in a range of different pre-school settings (centres) and used statistical approaches (multilevel modelling) that enable the identification of individual pre-school centre effects and to investigate the impact of pre-school and later school influences over different phases of education.

The current report focuses on students' academic attainment and progress in KS3 using Teacher Assessments (TA), measures of academic attainment in English, maths and science in Year 9 (age 14) and National Assessment test scores, measures of prior attainment taken in Year 6 (age 11+). In Year 9, variations in students' outcomes measured by TA levels were studied rather than aged standardised test scores as the KS3 National Assessment test data were not available for 2 of the 4 cohorts of students in the sample (due to a change in government policy)⁸. The TA levels data were available for approximately N=2643 (94%) and test scores were available for approximately N=1213 (43%) of the 'active' sample (N=2812).

Following the practice in previous phases of the project, the EPPSE 3-14 study continues to use a mixed methods approach (combining qualitative and quantitative methods) and an educational effectiveness design, including detailed statistical analyses of effectiveness and in-depth case studies of individual students and families (Sammons et al., 2005; Siraj-Blatchford et al., 2006; Sylva et al., 2010).

This report presents the results of analyses related to the influence of pre-school, primary and secondary school on students' academic attainments at the end of Year 9 and on their progress across KS3 from the end of Year 6 of primary school to the end of Year 9 in secondary school. Further analyses of students' social-behavioural development and attitudes to school in Year 9 will be reported in separate research reports (Sammons et al., 2011a; 2011b).

⁷ Full details of the original EPPE study are provided in a series of Technical Papers (see Appendix 1).

⁸ The KS3 National tests were abolished in October 2009.

Aims

The aims of the research were to:

- Investigate the associations between students' academic attainment in KS3 (Year 9, age 14) and background individual student, family and home learning environment (HLE) characteristics.
- Model students' current academic *attainment* in Year 9, and their *progress* over KS3.
- Explore the influence of pre-school experience, particularly in terms of attendance, quality and academic effectiveness on later academic outcomes.
- Examine the combined impact of the Home Learning Environment (HLE) and pre-school characteristics.
- Investigate the influence of primary school academic effectiveness on academic attainment and progress, when individual student, family and home learning environment (HLE) characteristics have been taken into account.
- Investigate the combined effect of pre-school and primary school experience on academic attainment.
- Assess whether the impact of pre- and primary school differs for more and less disadvantaged children.
- Investigate the influence of secondary school academic effectiveness and quality on academic attainment, when individual student, family and home learning environment (HLE) characteristics have been taken into account.
- Investigate the combined effect of secondary school experience with pre- and primary school experiences on academic attainment.
- Explore the effects of students self-perception and views of schools on academic attainment.

Multiple Imputation

Due to policy changes on the use of KS3 National Assessment tests, the EPPSE sample was left without KS3 test scores for two of four cohorts. Therefore, the present report uses the Teacher Assessments (TA) on English, maths and science as academic outcomes for the KS3 National Assessments, as these were available for all 4 cohorts of the study. It is acknowledged that TA levels are less finely differentiated than test scores and this has implications for the analysis.

Major longitudinal studies have been widely advocating the use of multiple imputation as a strategy to successfully deal with missing data. Multiple imputation of missing data has been adopted in this study to provide a valuable tool for dealing with missing data and maximize sample size. Multiple imputation is the statistical procedure that replaces the missing values with a set of predicted values (Little & Rubin, 1987). This procedure generates several imputed data sets, which are then analysed and the results combined according to Rubin's rule (Rubin, 1987). Two alternative multiple imputation techniques have been tested: the ICE user-written program available in STATA and AMELIA II available in R. Comparisons between results from non-imputed and imputed data have been conducted and presented simultaneously. It was deemed appropriate to impute data for students who had academic outcomes for three or more time points (considering from Baseline until Year 9). Therefore, the original sample (N=3172) was reduced to N=3002.

Analyses Strategy

The analyses employ a range of statistical techniques from simple descriptive and correlation analysis to multilevel (hierarchical) modelling to examine the influences on students' academic attainment and progress. This paper focuses on TA levels in English, maths and science as measures of academic attainment in Year 9 and age standardised National Assessment data at the end of Year 6 in English and maths as measured of prior attainment in studying progress across KS3. In addition, exploratory and confirmatory factor analysis has been used to identify underlying dimensions of KS2 HLE, school processes and affective outcomes such as academic self-concept or enjoyment of school.

Multilevel (hierarchical) regression was used to study the influence of various individual student, family, home learning environment (HLE) and neighbourhood factors as predictors of variation in students' Year 9 outcomes in the three core curriculum subjects. Additionally, the same analysis techniques were used to explore the pre-school, primary and secondary school influences on later academic attainment and progress during KS3. Earlier analyses enabled the calculation of value added estimates (residuals) of individual pre-school centre effects for the EPPSE 3-14 students who had attended a pre-school centre (see Sammons et al., 2002 for details). These value added measures of centre effectiveness have been included in subsequent analyses of students' educational outcomes in Year 9 of secondary school, to establish whether the effectiveness of the pre-school attended continues to show an impact on later academic attainment.

To examine the impact of primary school, measures of primary school academic effectiveness in English, maths and science have been derived from independent value added analyses of student progress for three successive full cohorts of children in English primary schools (2002-2004) using National assessment data sets matched between KS1 and KS2 over three years (see Melhuish et al., 2006a; 2006b). The impact of secondary school was explored using DfE indicators KS2-KS4 contextualised value added (CVA) measures and various Ofsted inspection judgements.

In addition, value added analyses of students' developmental progress were conducted to explore change over time in students' outcomes from Year 6 (end of KS2, age 11) to Year 9 (in KS3, age 14).

Structure of Report and Analyses

This report is divided into six sections. The first section provides background information concerning the characteristics of the EPPSE 3-14 sample and investigates whether particular groups of students show differences in their academic attainment in secondary school education. The attainment differences reported in Section 1.3.3 are 'raw' univariate attainment differences, whereas the effects reported in later sections are calculated 'net' of the influence of other predictors effects.

Section two examines the extent to which different individual student, family and home learning environment (HLE) background characteristics account for variations in students' English, maths and science outcomes. The 'net' influence of different background factors on students' attainments is explored. These analyses identify the unique (net) contribution of particular characteristics to variation in students' academic outcomes, while other influences are controlled. Thus, for example, the influence of family Socio-Economic Status (SES) is established while taking into account the influence of parents' qualification levels, income, ethnicity, birth weight, HLE etc. Results are reported in effect sizes (ES), a statistical measure of the relative strength of different predictors. In addition, estimates shown in Tables illustrate differences in terms of TA levels. It is of policy interest to establish the nature and strength of such background influences individually and collectively, as they are relevant to issues of equity and social inclusion.

The third section explores the continued influence of pre-school, primary and secondary school experience on students' academic outcomes at the end of Year 9. In the first phase of the earlier

EPPE research it was shown that pre-school experience gave children a better start to primary school in terms of higher academic attainment and improved social-behavioural outcomes. Lack of pre-school experience, particularly for more vulnerable groups of young children, was found to be a further disadvantage (Sammons et al., 2002; 2003). The effect of pre-school attendance was, in these earlier analyses, supplemented with measures of pre-school centre influence, namely the observed quality of pre-school provision (measured by the ECERS-R and ECERS-E scales) and pre-school centre effectiveness (measured by value added residual estimates based on cognitive progress during the pre-school period). The same children's measurements proved to be significant predictors of later academic attainment for the EPPSE sample measured at the end of primary school. Therefore, in this report we explore the potential lasting effects of attending pre-school on the academic attainment during secondary school as well. This section also addresses the question of differential pre-school effects for different groups of students, e.g., those from disadvantaged backgrounds. Similarly, the predictive influence of measures of primary school academic effectiveness⁹ on students' later academic outcomes in Year 9 was also explored. In addition, the analyses establish whether certain groups of students are more sensitive to the academic effectiveness of the primary school they attended than other students. Additional analyses explored the combined impact of different characteristics of pre-school experience (quality and effectiveness) and primary school academic effectiveness. The predictive influences of measures of secondary school academic effectiveness¹⁰ and quality measured by Ofsted inspection judgements were also studied. Additional analyses explored the combined impact of different characteristics of secondary school academic effectiveness with pre-school experience (quality and effectiveness) and primary school academic effectiveness.

Section four presents results of analyses that explored students' academic progress from the end of Year 6 at primary school to Year 9 in secondary school. Value added multilevel analyses of EPPSE 3-14 students' academic progress across KS3 have been conducted; these analyses control for prior attainment (at the end of Year 6) in analysing progress over time. They are used to complement the contextualised models of attainment to establish how far background factors and educational measures of pre- and primary schools also predict progress across KS3.

Section five shows the results of the analyses that examined the predictive influences of school and teaching processes as well as the influences of students' self-views on the various measures of secondary academic outcomes in Year 9.

The final section summarises the results drawing together the main findings, conclusions and implications for policy and practice.

⁹ These were value added academic effectiveness measures for primary schools that were calculated independently using National Assessment data for all primary schools in England linking KS1 and KS2 results) (Melhuish et al., 2006a; 2006b).

¹⁰ These were KS2-KS4 CVA academic effectiveness measures for secondary schools provided by DfE.

1. Characteristics of the Sample at the End of Year 9

The present study relies on the original EPPE sample. The original sampling procedure is described fully in the EPPE Technical Paper 1 (Sylva et al., 1999). Briefly, six English Local Authorities (LAs) in five regions were selected to participate in the research with students drawn from six main types of pre-school provision: nursery classes, playgroups, private day nurseries, Local Authority (LA) day nurseries, nursery schools and integrated (i.e., combined centres that integrate education and care) centres. In order to enable comparison of centre and type of provision effects the project was designed to recruit approximately 500 students, 20 in each of 20-25 centres, from the various types of provision. In some LAs certain forms of provision were less common and other forms more typical. Within each LA, centres of each type were selected by stratified random sampling and, due to the small size of some centres in the project (i.e. rural playgroups) more of these centres were sampled than originally proposed, bringing the centre sample total to 141 centres. In all 2,857 children in the pre-school sample were tracked to entry to reception class. An additional sample of 315 'home' children (those who had not attended a pre-school centre) was recruited at entry to primary school, for comparison with those who had attended a pre-school centre, bringing the total sample to 3,172.

Since the start of the study 14 years ago, the EPPE students have been assessed on their cognitive and social-behavioural development at various time points. This report refers to two time points at which students completed cognitive assessments: at the end of Year 6 (age 11) and at the end of Year 9 (age 14).

On 24 October 2008 there was an announcement by the Secretary of State that the current testing regime for KS3 would cease. Although Teacher Assessment (TA) levels would still be a requirement there was no statutory obligation on schools to conduct National Assessment test scores. This posed a challenge for the EPPSE project, as two of the four cohorts from the EPPSE sample were left without results for the KS3 National Assessment test scores. Thus, the present report uses mainly the TA levels in English, maths and science as academic outcomes and not the results of the KS3 National Assessment test scores (although descriptive statistics with these academic outcomes are included in Appendix 3). Furthermore, multiple imputation was used to overcome the missing data in both TA and test scores.

To make the imputation model more robust, we started with the original sample (N=3172) and selected only the cases that had academic outcomes for three or more time points (considering from Baseline until Year 9). For Year 9, having either a test score or a TA was considered a valid data point. Cases were included only if they satisfied this criterion simultaneously for both English and maths (thus, for example if a student had the 3 valid points for maths but not for English, this student was not included in the final sample). Moreover, an additional requirement was imposed over the sample size: cases were included only if they did not have missing data on more than five background variables (e.g., family SES, health problems, salary). The final sample size included N=3002 students (see more details on multiple imputation in Appendix 10).

This section provides descriptive statistics for the sample at the end of Year 9. Details of the main findings of the analyses conducted on students' attainment and progress up to the end of KS2 (Year 6) can be found in Sammons et al. (2008a).

1.1. Original Data

Table 1.1 and Table 1.2 provide a brief summary of the characteristics of the EPPSE 3-14 sample for which we have valid academic outcomes (TA) at the end of Year 9 (see Tables on test scores in Appendix 2). Very similar proportion of adolescents had valid data on English, maths and science TA levels ($N_{\text{English}}=2574$; $N_{\text{maths}}=2574$; $N_{\text{science}}=2575$). As a result, the distributions of these students within different demographic characteristics were also very similar.

In terms of gender distribution, 51% (almost 52% of those with valid maths TA) were males and 49% per cent females (48% of those with valid maths TA). The majority of the adolescents (74%) were of White UK heritage, while Bangladeshi young people represented the smallest ethnic group (1%).

Regarding family structure, 17% of the young people lived in large families (having 3 or more siblings) while more than half of the sample had one or two siblings (64%). Table 1.1 also shows the distribution of the Early Years Home Learning Environment (HLE) index which is a combined measure of aspects of the quality of the home learning environment in the early years (see Appendix 5 and Melhuish et al., 2008a; Sammons et al., 2002; 2003; 2004a). A number of measures collected at entry to the study from the parent interview provided an indication of aspects of the HLE in the early years. These are based on the frequency of engagement in specific activities involving the child such as, teaching the alphabet, reading to the child, listening to the child read, taking the child to the library etc. (as reported by the parents at interview). Over 40% of the adolescents belonged to families where a good or very good home learning environment in the Early years was present. A very poor HLE characterised around 10% of the sample. In the present sample, 13% of the adolescents had not attended any type of pre-school (the 'home' group) before entering primary school.

In terms of parents' qualification, almost 13% of mothers and fathers had a degree or a higher degree. With respect to the family's social economic status¹¹ (SES), more than 30% were classified in the professional category. A higher percentage (50%) were classified as skilled (either manual or non manual) and only 2.9% were unemployed. Nearly 20% of the students were eligible or receiving free school meals (FSM) in Year 9¹². Almost half of the sample (46%) lived in families with very low (below £17,500) or no income. Seventy- eight percent did not have any SEN provision, while only 3% had a full SEN statement.

¹¹ Family SES was calculated by considering the highest SES status of the mother or the father.

¹² The FSM information collected with the EPPSE Year 9 Pupil Profile Questionnaire had a high percentage of missing values (46%). Therefore, this information was combined with the FSM information available from the National Pupil Database. Additionally, it is important to stress that the EPPSE variable represents the students who actually receives FSM, while the NPD variable indicates the students who are eligible to receive FSM. NPD 's definition of the FSM eligibility: "Pupils should be recorded as eligible (true) only if a claim for free school meals has been made by them or on their behalf by parents and either (a) the relevant authority has confirmed their eligibility and a free school meal is currently being provided for them, or (b) the school or the LEA have seen the necessary documentation (for example, an Income Support order book) that supports their eligibility, and the administration of the free meal is to follow as a matter of process. Conversely, if students are in receipt of a free meal but there is confirmation that they are no longer eligible and entitlement will be revoked, false should be applied."

Table 1.3 and Table 1.4 present the same demographic characteristics for the students who had missing data on the academic outcomes measured as TA levels. Males were slightly over represented in the missing TA data group. Those with missing TA data were significantly more likely to have parents who were highly qualified (degree or higher degree) or be of high family SES (Professional non-manual).

1.2. Imputed Data

Table 1.5 and Table 1.6 compare the distribution of the original and imputed characteristics of the EPPSE 3-14 sample at the end of Year 9. Some of the demographic variables did not require imputation as we had the information for the full sample (i.e., gender, type of pre-school attended). However, we had missing values on ethnicity for 2 cases and these were not imputed. The distributions of the imputed background characteristics are similar to the original distributions.

1.3. Academic assessments

To take account of development and age, the study uses different assessment instruments for academic outcomes at different time points:

- Year 6: National Assessment at KS2: English and maths (all 4 cohorts)
- Year 9: National Curriculum Level Awarded for Teacher Assessment at KS3: English, maths and science (all 4 cohorts)
- Year 9: National Assessment at KS3: English and maths (Cohort 1 and 2)¹³

TA levels were obtained from the National Pupil Dataset (NPD) at the end of Year 9 or directly from the schools when these were missing. TA levels are less differentiated measures of attainment compared to tests as the levels are only ordinal categories placing students into a few ranked attainment groups. In Year 9, students were awarded TA levels from level 1 to level 8 and the same levels applied to English, maths and science.

National Assessment data were collected for the sample at the end of Year 6 and Year 9. Similarly to the TA levels, test levels were also ordinal categories. In Year 6, the students were classified in 6 groups from working towards level 1, level 1 through to level 6. However in Year 9, the levels of the National Assessments were awarded differently for English and maths. For English, students were categorised in 6 groups from working towards level 3 up to level 7. For maths, students were classified in 5 groups, although further categorised based on the type of tiers. For example, the levels for Tier 3-5 went from 1 through 5, while for Tier 6-8, levels went from 4 to 8.

In addition to test levels, data were also collected on students' individual test scores within levels. This allowed the creation of more finely differentiated outcome measures (which are referred to as decimalised levels) for the multilevel analysis.

For students who scored high enough to attain a valid level for the National Assessment test taken, their decimalised score was calculated as follows:

$$\text{Decimalised Level} = \text{Level Achieved} + \frac{\text{Raw Score} - \text{Lowest Valid Score For That Level}}{\text{Lowest Valid Score For Higher Level} - \text{Lowest Valid Score For That Level}}$$

Furthermore, to ensure comparability over time, an internal age standardisation and normalisation procedure was applied to the decimalised data. This procedure takes account of age effects within one school year: hence age of student does not feature as a significant predictor of attainment / progress although it was included in the models. The scores presented in this paper are internally standardised to a mean of 100 and a standard deviation of 15. Therefore, all students scoring better than 100 at a certain time point are scoring at or above the attainment level expected for their chronological age (belong to the upper half of the sample of that assessment, controlling for age effects). Due to the use of internally standardised attainment scores, the scores can only be used to investigate the progress or improvement of certain groups of students *relative* to the total EPPSE 3-14 sample, but cannot be used to show *absolute* progress over time.

¹³ Due to the very high proportion of missing data on the National Assessment test scores, this report focuses on the TA levels. However, analyses were also conducted on the original and imputed test scores.

1.3.1. Descriptive Statistics of Academic Outcomes (Original versus Imputed Data)

Figure 1.1 presents the distribution of TA levels in English, maths and science (see Appendix 3 for similar distributions for National Assessment results). Table 1.8 and Table 1.9 show the basic descriptive statistics for the outcomes considered on the original data and the multiple imputation data. The descriptive statistics are very similar in terms of means and standard deviations, but there is a slight increase in both the means and the standard deviations on the multiple imputed data sets.

Figure 1.1: Distributions of Different Measures of Academic Attainment at Year 9 – Original Data

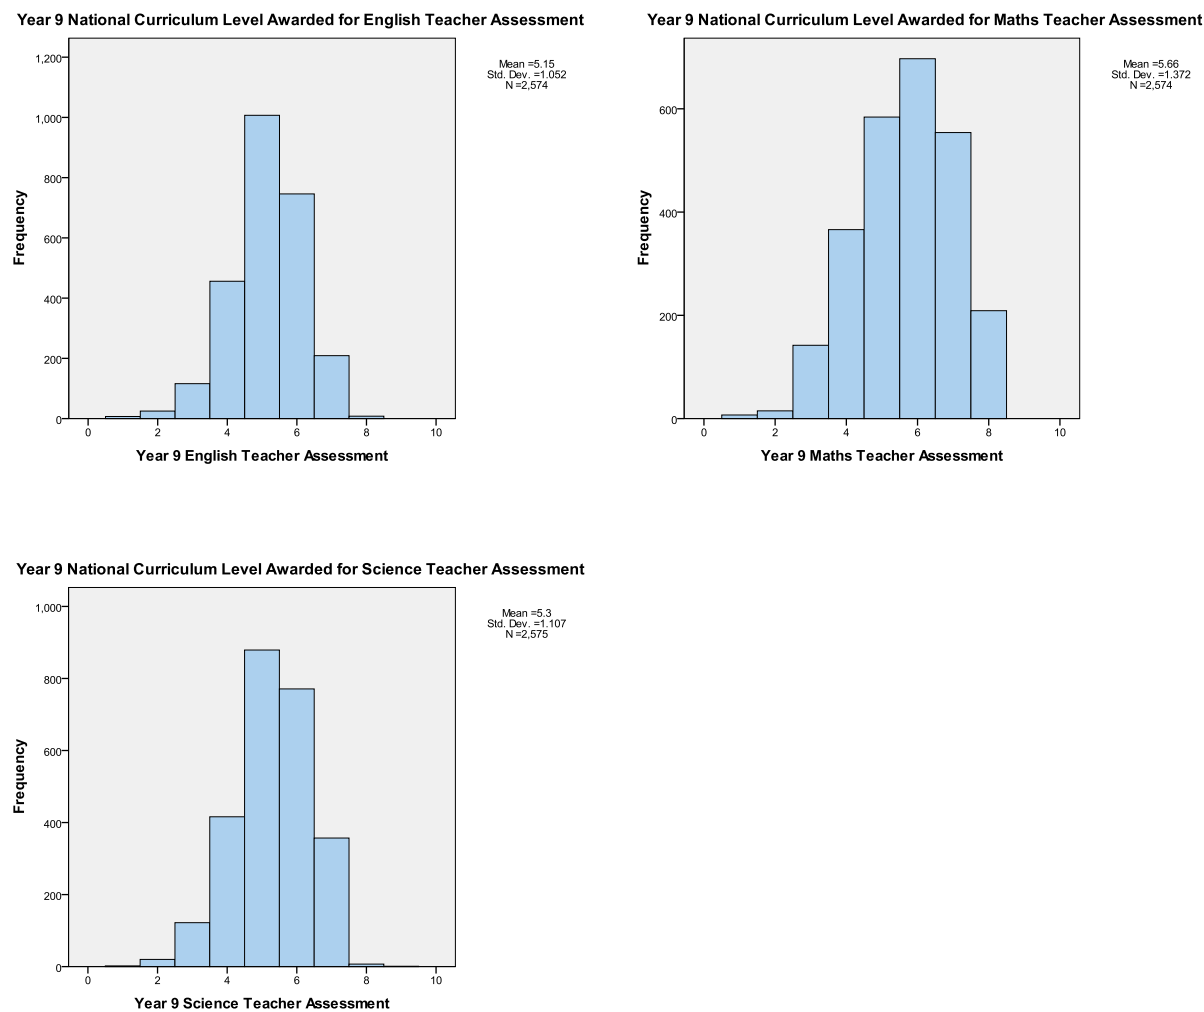

Table 1.7: Distributions of Different Measures of Academic Attainment at Year 9 – Original Data

	Year 9 English TA		Year 9 Maths TA		Year 9 Science TA	
National Curriculum Level Awarded	N	%	N	%	N	%
1	7	.3	7	.3	2	.1
2	25	1.0	15	.6	20	.8
3	116	4.5	142	5.5	122	4.7
4	456	17.7	366	14.2	416	16.2
5	1007	39.1	584	22.7	879	34.1
6	746	29.0	697	27.1	772	30.0
7	209	8.1	554	21.5	357	13.9
8	8	.3	209	8.1	7	.3
Total	2574	100.0	2574	100.0	2575	100.0

Table 1.8: Descriptive Statistics of Academic outcomes at Year 9 – Original Data

	N	Min	Max	Mean	Std. Dev.
Year 9 English Teacher Assessment	2574	1	8	5.15	1.05
Year 9 Maths Teacher Assessment	2574	1	8	5.66	1.37
Year 9 Science Teacher Assessment	2575	1	8	5.30	1.10
Total	3002				

Table 1.9: Descriptive Statistics of Academic outcomes at Year 9 – Imputed Data

	N	Min	Max	Mean	Std. Dev.
Year 9 English Teacher Assessment	3002	1	8	5.18	1.06
Year 9 Maths Teacher Assessment	3002	1	8	5.70	1.38
Year 9 Science Teacher Assessment	3002	1	8	5.32	1.11
Total	3002				

1.3.2. Associations between Students' Attainment in Different Outcomes and over Time

Correlations explore the associations between students' attainment on different outcomes and over time.¹⁴ Students' attainment (English & maths) in Year 9 was strongly and positively correlated ($r_{\text{orig}}=0.72$; $r_{\text{imp}}=0.65$), indicating those who do well in English generally also do well in maths at the end of Year 9, while those who score poorly on one also tend to do poorly in the other. This correlation is higher than the equivalent correlation between English and maths scores at the end of Year 6 ($r=0.66$). Additionally, the relationships between test scores and TA levels in Year 9 were very strong ($r_{\text{English}}=0.75$, $r_{\text{maths}}=0.89$) for the original data; however, slightly lower for the imputed data ($r_{\text{English}}=0.66$, $r_{\text{maths}}=0.80$).

The academic scores are not only highly associated with each other but also show moderate to high correlations with prior attainment (see Table 1.10, Table 1.11 and Table 1.12). A strong relationship was found for attainment in English in Year 9 and Year 6 ($r_{\text{orig}}=0.74$; $r_{\text{imp}}=0.78$), while attainment in maths was also strongly correlated between Year 9 and Year 6 ($r_{\text{orig}}=0.86$; $r_{\text{imp}}=0.87$).

Table 1.10: Correlations Between Students' Standardised Academic Outcomes (English and Maths) and Prior Attainment – Original Data

	Year 9 English	Year 9 Maths	Year 9 English	Year 9 Maths
	National Assessment Standardised Scores	National Assessment Standardised Scores	TA	TA
Year 9 English National Assessment Standardised Scores	1		0.75 (N=1105)	0.68 (N=1103)
Year 9 Maths National Assessment Standardised Scores	0.72 (N=1133)	1	0.70 (N=1143)	0.89 (N=1144)
Year 6 English National Assessment Standardised Scores	0.74 (N=1100)	0.66 (N=1125)	0.70 (N=2416)	0.65 (N=2413)
Year 6 Maths National Assessment Standardised Scores	0.60 (N= 1107)	0.86 (N=1135)	0.61 (N=2426)	0.82 (N=2424)

On the original data, we tested the correlations of Year 9 attainment in science (measured by both standardised test scores and TA levels) and Year 9 and Year 6 attainment in English and maths (Table 1.11). The results indicate that the attainment in science is related more strongly to attainment in maths than to attainment in English, regardless of how the science attainment was measured (standardised test score or TA levels). However, the correlations between standardised tests were higher than the correlations between TA levels and standardised test scores.

¹⁴ A correlation is a measure of statistical association that ranges from + 1 to -1.

Table 1.11: Correlations Between Students' Standardised Academic Outcomes (Science, English and Maths) and Prior Attainment – Original Data

	Year 9 Science	Year 9 Science
	National Assessment Standardised Scores	TA
Year 9 English National Assessment Standardised Scores	0.77 (N=1133)	0.66 (N=1125)
Year 9 Maths National Assessment Standardised Scores	0.87 (N=1172)	0.79 (N=1146)
Year 9 Science National Assessment Standardised Scores	1	0.82 (N=1147)
Year 6 English National Assessment Standardised Scores	0.68 (N=1121)	0.64 (N=2417)
Year 6 Maths National Assessment Standardised Scores	0.73 (N= 1131)	0.68 (N=2427)

Table 1.12: Correlations Between Students' Standardised Academic Outcomes (English and Maths) and Prior Attainment – Imputed Data (N=3002)

	Year 9 English	Year 9 Maths	Year 9 English	Year 9 Maths
	National Assessment Standardised Scores	National Assessment Standardised Scores	TA	TA
Year 9 English National Assessment Standardised Scores	1		0.66	0.62
Year 9 Maths National Assessment Standardised Scores	0.65	1	0.63	0.80
Year 6 English National Assessment Standardised Scores	0.78	0.67	0.72	0.66
Year 6 Maths National Assessment Standardised Scores	0.63	0.87	0.63	0.81

At this stage, the high correlations between academic assessments at different time points indicate that the assessments are measuring similar aspects of attainment. The impact of earlier attainment as predictors for later attainment will be explored further in Section 4. Of particular interest will be the 'net' influence of different student, background and home learning environment (HLE) characteristics in Year 9, when controlling for prior attainment of the students, as this will indicate whether some groups make more or less progress relative to others during KS3.

1.3.3. Differences in Attainment for Different Groups of Students

This section presents figures on the differences in academic attainment in Year 9 measured by TA levels for student sub-groups of particular interest. Previous analyses reported significant differences in academic outcomes for different groups at various time points (e.g., pre-school, entry to primary school, at the end of Year 1, at the end of Year 2, at the end of Year 5 and at the end of Year 6) (Sammons et al., 2004b; 2004c; 2007a; 2008a). These particular student groups refer to individual student, family and Early Home Learning Environment (HLE) characteristics and were also used as predictors for different aspects of the students' social-behavioural development (see Sammons et al., 2011a).

The reported differences represent the 'raw' differences in the average results for different student sub-groups as there is no control for the influence of any other variables. This means, for example, if there are sizeable differences between individual ethnic groups, these differences could also be due, at least in part, to family SES or to language differences between the ethnic groups. Section 2

of this report provides more detailed statistical analyses of these patterns using multilevel models to explore the 'net' contribution of different factors and reports the relevant effect sizes, controlling for other factors. It will also address the issue of change in 'net' contribution of different factors over time in terms of effect sizes¹⁵.

Gender

At younger ages females were found to score higher in academic attainment. At the end of KS3 (Year 9), this pattern of average results was found for the original TA levels in English, but not for the average results for TA levels in maths or science, where, as a group, females and males tend to have similar results, although the variation (shown by the *SD* is slightly higher for males) (see Table 1.13).

Table 1.13: Academic Attainment in Year 9 by Gender – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	Gender	Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	Male	5.0	1.1	1311	5.0	1.1	1543
	Female	5.4	1.0	1263	5.4	1.0	1459
Year 9 Maths Teacher Assessment	Male	5.7	1.4	1306	5.7	1.4	1543
	Female	5.7	1.3	1268	5.7	1.3	1459
Year 9 Science Teacher Assessment	Male	5.3	1.2	1312	5.3	1.2	1543
	Female	5.3	1.0	1263	5.4	1.1	1459

¹⁵ Effect sizes (ES) are a statistical measure of the relative strength of different predictors.

Ethnicity

Consistent with previous findings for the students at younger ages, Pakistani students continue to have at the end of Year 9 the lowest attainment levels in English and maths, but also in science (see Table 1.14). Students of Indian heritage have the highest average results in TA levels.

Table 1.14: Academic Attainment in Year 9 by Ethnic Groups - Original and Imputed Data

	Ethnicity	Original Data			Imputed Data Pooled Sample		
		Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	White European Heritage	5.1	1.2	85	5.1	1.2	110
	Black Caribbean Heritage	5.1	1.0	101	5.0	1.0	109

	White UK Heritage	5.3	1.1	1911	5.4	1.1	2206

Parents' Qualification Level

Table 1.15 shows the attainment in English, maths and science by the mother's highest qualification level. This variable proved to be a strong predictor of students' academic results at earlier time points in the EPPE 3-11 research (entry to pre-school, at entry to primary school, end of Year 1, end of Year 2, end of Year 5, and end of Year 6). At the end of Year 9, mother's qualification is still a significant predictor of the academic Attainment, regardless of how this was measured (see Appendix 4 for raw differences in test scores). Adolescents whose mothers have a degree or higher degree show the highest average TA levels in English, maths, and science ($M_{\text{English TA}}=6.0$; $M_{\text{maths TA}}=6.7$; $M_{\text{science TA}}=6.2$). The lowest attainment is seen for students whose mothers have no qualifications ($M_{\text{English TA}}=4.6$; $M_{\text{maths TA}}=5.0$; $M_{\text{science TA}}=4.7$).

Table 1.15: Academic Attainment in Year 9 by Mother's Highest Qualification – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	Mother's Highest Qualification	Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	None	4.6	1.0	559	4.6	1.0	651
	Vocational	5.1	1.0	386	5.1	1.0	448
	Academic Age 16	5.1	1.0	1002	5.1	1.0	1120
	Academic Age 18	5.5	.9	197	5.5	0.9	247
	Degree or Higher Degree	6.0	.9	323	5.9	0.9	492
	Other professional	5.7	.9	37	5.6	1.0	44
Year 9 Maths Teacher Assessment	None	5.0	1.3	558	5.0	1.3	651

	Vocational	5.3	1.0	386	5.3	1.0	448
	Academic Age 16	5.3	1.0	1001	5.3	1.1	1120
	Academic Age 18	5.8	.9	197	5.7	1.0	247
	Degree or Higher Degree	6.2	.9	322	6.0	0.9	492
	Other professional	5.9	.9	38	5.8	0.9	44

Family Socio-Economic Status (SES) and Free School Meals (FSM)

Family SES is measured by the highest mother's or father's current or most recent employment status and showed a significant association with students' attainment levels at the end of Year 9. Even though the KS3 SES is significantly related to academic outcomes in Year 9, the earliest measure of family SES is more powerful in predicting test scores and TA levels. Therefore, the latter is presented here and was used in the multilevel models. The highest teacher evaluations were gained by students from higher SES group (e.g., the results for professional non manual are: $M_{\text{English TA}}=5.9$; $M_{\text{maths TA}}=6.7$; $M_{\text{science TA}}=6.2$). The lowest attainment is seen for students whose family SES was categorised as unskilled ($M_{\text{English TA}}=4.6$; $M_{\text{maths TA}}=4.9$; $M_{\text{science TA}}=4.7$).

Table 1.16: Academic Attainment in Year 9 by Family SES (Early Years) – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	Family SES	Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	Professional Non Manual	5.9	.8	165	5.9	0.9	266
	Other Professional Non Manual	5.5	.9	605	5.5	1.0	756
	Skilled Non Manual	5.2	1.0	876	5.1	1.0	967
	Skilled Manual	4.8	1.0	398	4.8	1.0	450
	Semi Skilled	4.7	1.1	349	4.7	1.1	400

	Never Worked	4.9	1.2	74	4.9	1.2	87

Students' eligibility for free school meals (FSM) provides an indicator of low family income (although it is recognised that not all students take up their entitlement). Table 1.17 shows that students who are reported to be eligible to receive free school meals (FSM) have lower average attainment on academic assessments compared to more advantaged families. The attainment gap is slightly larger for maths than for English or science. This pattern of results is in line with that found at younger ages, indicating that social disadvantage continues to show a statistically significant association with attainment.

Table 1.17: Academic Attainment in Year 9 by Free School Meals – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	FSM	Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	No FSM	5.3	1.0	2041	5.3	1.0	2431
	FSM	4.6	1.1	504	4.6	1.1	571
Year 9 Maths Teacher Assessment	No FSM	5.8	1.3	2040	5.9	1.3	2431
	FSM	5.0	1.3	504	4.9	1.3	571
Year 9 Science Teacher Assessment	No FSM	5.4	1.1	2044	5.5	1.1	2431
	FSM	4.7	1.1	503	4.7	1.1	571

Special Educational Needs (SEN)

As might be expected, students identified in secondary school records as having any type of SEN showed significantly lower attainment in English, maths and science (see Table 1.18). Furthermore, those identified with a full SEN statement had the lowest results in all subjects.

Table 1.18: Academic Attainment in Year 9 by SEN – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	SEN Status	Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	No special provision	5.4	.9	1976	5.4	0.9	2346

	Statement of SEN	3.7	1.3	83	3.9	1.4	105

Early Years Home Learning Environment (HLE)

The Early Years HLE had been shown to have a strong significant positive impact on students' academic outcomes at earlier time points. At the end of Year 9, the Early Years HLE index still shows a strong linear relationship with average academic attainment; the better the Early home learning, the higher the TA levels at Year 9 (see Table 1.19, but also Appendix 4).

Table 1.19: Academic Attainment in Year 9 by Early Years HLE Index – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	Early Years HLE	Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	0-13	4.7	1.1	238	4.6	1.1	293
	14-19	4.9	1.1	576	4.9	1.1	665
	20-24	5.1	1.0	621	5.1	1.0	732
	25-32	5.3	1.0	779	5.4	1.0	965
	33-45	5.7	.9	278	5.7	0.9	347
Year 9 Maths Teacher Assessment	0-13	5.1	1.4	235	5.0	1.4	293
	14-19	5.4	1.4	576	5.4	1.4	665
	20-24	5.6	1.3	623	5.6	1.3	732

	14-19	5.1	1.1	579	5.1	1.1	665
	20-24	5.3	1.1	622	5.3	1.1	732
	25-32	5.5	1.0	777	5.5	1.0	965
	33-45	5.9	.9	277	5.9	1.0	347

The Key Stage 1 Home Learning Environment (HLE)

Table 1.20 shows the correlations of different dimensions of the KS1 HLE and Early Years HLE. Most of the correlations are statistically significant although modest in size. This might be due to the way the two HLEs were measured: the Early Years HLE was obtained from parents' interviews, while KS1 HLE was obtained from parents filling in questionnaires. Additionally, modest relationships could be expected as over time there are important changes in the children's HLE activities at home during pre-school and these are different from the activities performed at older ages.

Table 1.20: Correlations Between Early Years HLE and KS1 HLE Factors – Original Data

	KS1 HLE Computing	KS1 HLE Interactions	KS1 HLE Outings	KS1 HLE Play
Early Years HLE	0.04 ^{ns} (N=1978)	0.15 (N=1978)	0.34 (N=1978)	0.14 (N=1978)
KS1 HLE Interactions	-0.004 ^{ns} (N=2049)			
KS1 HLE Outing	-0.0008 ^{ns} (N=2049)	0.002 ^{ns} (N=2049)		
KS1 HLE Play	-0.003 ^{ns} (N=2049)	-0.003 ^{ns} (N=2049)	-0.0009 ^{ns} (N=2049)	

When we do not control for any individual or family characteristics, the differences in academic attainment show that a medium level of KS1 HLE related to computing activities was associated with higher levels in all three subjects. Similar results were obtained for KS1 HLE related to parent-child interactions and expressive play (see Table 1.22 and Table 1.24). Conversely, a higher frequency of parent-child activities outside the home was associated with better academic outcomes in English, maths and science (see Table 1.23).

Table 1.21: Academic Attainment in Year 9 by KS1 HLE Computing – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	KS1 HLE Computing	Mean	Std. Dev.	N	Mean	Std. Dev.	N

The Key Stage 2 Home Learning Environment (HLE)

Similar to the correlations between Early Years HLE and KS1 HLE, KS2 HLE relates modestly to previous HLE (see Table 1.25). The differences in TA average levels show that both medium and high KS2 HLE were associated with better academic outcomes in English, maths and science (see Table 1.26 and Table 1.27). As previously noted, these results should be taken cautiously as they are not net effects.

Table 1.25: Correlations Between Early Years HLE and KS1 HLE Factors – Original Data

	KS2 HLE Educational Computing	KS2 HLE Individual Activities
Early Years HLE	0.18 (N= 1832)	0.29 (N=1832)
KS1 HLE Computing	0.22 (N= 1485)	0.03 ^{ns} (N= 1485)

Pre-school Attendance

Findings from earlier analyses (start of primary school, at the end of Year 1, Year 2 and Year 6) showed beneficial effects of attending a pre-school on academic outcomes when compared with not attending a pre-school. At the end of Year 9, students who had attended pre-school still have higher average TA levels than students who had not attended pre-school (see Table 1.28).

Due to the very different characteristics of the 'home' group (for example, disadvantaged students are over-represented in this group) and very different characteristics of students who went to different types of pre-school centre, these raw differences need to be interpreted with considerable caution. Further analyses are required to separate the 'net' pre-school effects from those related to background characteristics. Section 3 investigates the impact of attendance, quality and effectiveness of pre-school in more detail, controlling for the influence of differences in students' background characteristics.

Table 1.28: Academic Attainment in Year 9 by Pre-school Attendance – Original and Imputed Data

		Original Data			Imputed Data Pooled Sample		
	Pre-school Attendance	Mean	Std. Dev.	N	Mean	Std. Dev.	N
Year 9 English Teacher Assessment	Pre-school Experience	5.2	1.0	2325	5.2	1.0	2721
	No Pre-school Experience	4.7	1.1	249	4.8	1.1	281
Year 9 Maths Teacher Assessment	Pre-school Experience	5.7	1.4	2328	5.8	1.4	2721
	No Pre-school Experience	5.0	1.4	246	5.1	1.4	281
Year 9 Science Teacher Assessment	Pre-school Experience	5.4	1.1	2325	5.4	1.1	2721
	No Pre-school Experience	4.8	1.1	250	4.8	1.1	281

It would be inappropriate to explore any continuing influence of pre-school, primary or secondary school on subsequent educational outcomes at the end of Year 9 unless proper statistical control is made of the influence of intake differences. The next section therefore examines the net influence of different individual student, family and HLE characteristics in contextualised multilevel statistical models, which identify and separate the various influences simultaneously. The additional 'net' influence of pre-school, primary and secondary school experience are then explored for the whole EPPSE 3-14 sample and for relevant sub-groups.

2. Students' Academic Attainment at the End of Year 9 in Secondary School: The Impact of Different Individual Student, Family and Home Learning Environment (HLE) Characteristics

This section presents the results of contextualised multilevel analyses establishing the pattern of relationships between various individual student, family and HLE characteristics and students' academic attainment at the end of Year 9. Background details concerning the students' earlier childcare experiences, health, family and HLE during the pre-school period were obtained from parental interviews conducted when students entered the EPPE study, a parent questionnaire completed by the parents when students were in KS1 of primary school education and a parent questionnaire completed by the parents when students were in KS2 of primary school education.

As potentially influencing background factors, the following measures have been used in the analyses:

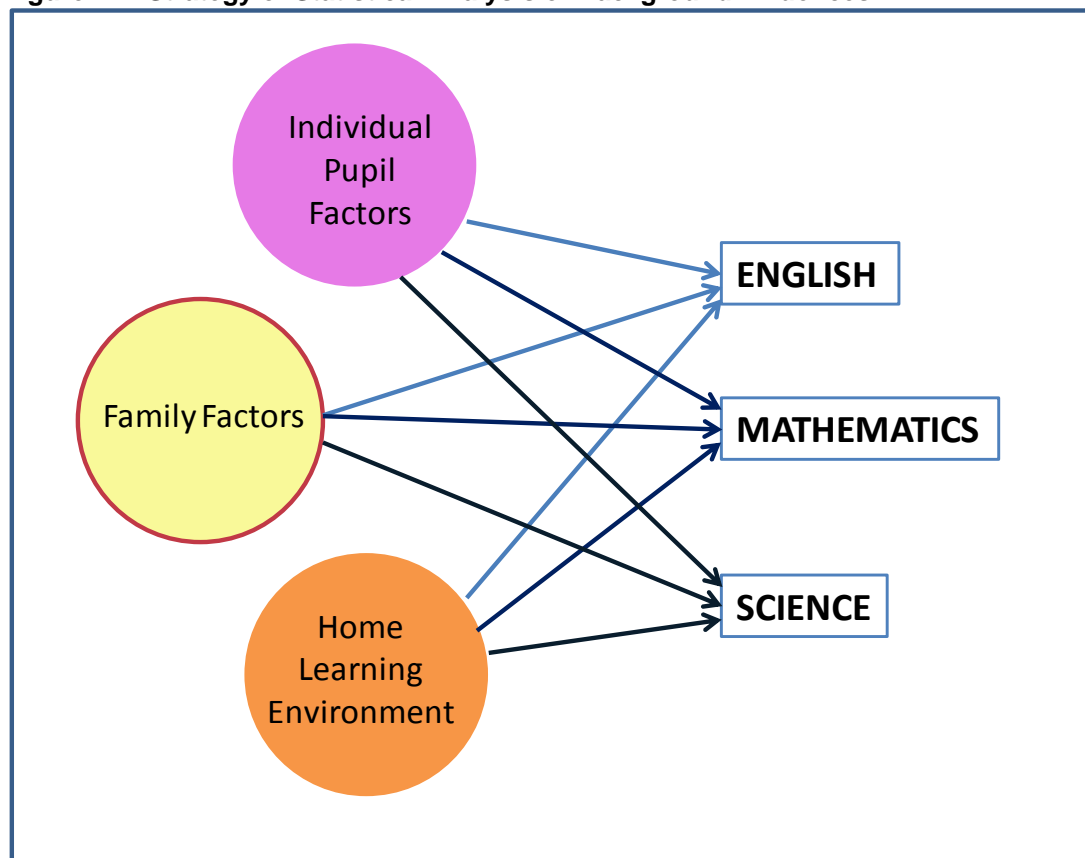

- Individual student factors (i.e., gender, birth weight, number of siblings, early developmental problems, early behavioural problems, early health problems, ethnicity).
- Family factors (i.e., socio-economic status [SES], parent's qualification levels, family income¹⁶).
- Home learning environment (HLE) in the early years (parents reported how often they read to the child, taught the child the alphabet, played with letters & numbers, taught songs & nursery rhymes, painted & drew etc.) before starting primary school.
- Parental activities during KS1 such as the frequency of reading to the child, taking the child out to educational visits, computing activities, play, etc. (see Appendix 5 for details of these measures).
- KS2 HLE included activities such as computing, playing, reading etc. (see Appendix 5 for details of these measures).

Figure 2.1 illustrates the strategy of the statistical analysis. The analyses investigated the associations between academic attainment and individual student, family and HLE characteristics when the students reach the end of Year 9 of secondary school education¹⁷. The analysis of the influence of individual student, family and HLE characteristics on academic outcomes is an important step as only on this basis, is it possible to separately identify and quantify the 'net' influence of pre-school, primary school education and secondary school. These influences will be explored in Section 3. The extent of differences in TA levels attributable to student background is also of considerable policy interest given the equity implications for later progress at school. The 'net' effects of particular individual student, family and HLE characteristics reported in this section were derived by contextualised multilevel analyses and therefore take into account any clustering related to the secondary school attended.

¹⁶ Marital status at KS2 was also included in initial analysis but did not prove significant.

¹⁷ It should be noted that all the analyses also accounted for associations between the predictors which could have been illustrated by additional arrows. For simplicity these arrows are not shown in Figure 2.1.

Figure 2.1: Strategy of Statistical Analysis of Background Influences

2.1. Null Models

In order to control for potential secondary school influences and to take account of the clustering in the data, multilevel analyses were used to partition the variance in the TA levels that is attributable to the school (Level 2) and the individual student (Level 1). This models the effects of clustering in the data (because students are nested in schools) and is widely recognized as essential in studying school influences (Creemers, Kyriakides & Sammons, 2010; Goldstein, 1995; 2003; Teddlie & Reynolds, 2000).

Table 2.1, Table 2.3 and Table 2.5 show the null models for TA levels in English, maths and science. For English TA levels, the school and student level variances are very similar for the original and imputed data. Similarly, for maths and science, the imputed models show similar variances at both student and school levels on the original data (with the exception for science, where the school level variance for imputed data is slightly higher than the corresponding variance on the original data). These initial results suggest that the imputation procedure was robust in relation to the multilevel structure of the data set.

The intra-school correlations (ICC) for all three academic outcomes show that there is significant school level variation (approximately 20-24%) so that pursuing the analyses with multilevel models is essential to avoid bias in estimating the effects of the predictors.

2.2. Individual Measures

Examining the associations between individual factors and attainment in English TA levels in Year 9, we found that age, gender, birth weight, early developmental and behavioural problems, and family size were statistically significant predictors. Their relative strength is shown by the effect sizes (ES) in Table 2.7. For maths at the end of Year 9 the following child characteristics are found to have a statistically significant net effect: gender, birth weight, ethnicity and early development and behavioural problems. Their relative strength is shown by the ES in Table 2.8. Regarding the academic attainment in science, predictors such as age, birth weight, ethnicity and early development problems had statistically significant net effects (see the specific ES in Table 2.9). The overall models are presented in Appendix 6.

Age

As the main academic outcomes were TA levels, these were not age standardised. Therefore, in the contextualised models we found a statistically significant age effect for English ($ES_{\text{Orig}}=0.19$; $ES_{\text{Imputed}}=0.19$), maths ($ES_{\text{Orig}}=0.15$; $ES_{\text{Imputed}}=0.15$) and science TA levels ($ES_{\text{Orig}}=0.16$; $ES_{\text{Imputed}}=0.15$). Older students tend to perform better than younger ones in English, maths and science.

Gender

Females obtained higher TA levels in English than males ($ES_{\text{Orig}}=0.46$; $ES_{\text{Imputed}}=0.41$). This result is consistent with results at earlier time points. Additionally, at earlier time points, girls also showed statistically significantly higher attainment in maths than boys. However, male students now tend to show a slightly higher attainment than females in maths, although the difference is not statistically significant.

Birth Weight

Students who were born with very low birth weight had statistically significantly lower attainment in English ($ES_{\text{Orig}}=0.37$; $ES_{\text{Imputed}}=0.53$), maths ($ES_{\text{Orig}}=0.40$; $ES_{\text{Imputed}}=0.59$) and science ($ES_{\text{Orig}}=0.35$; $ES_{\text{Imputed}}=0.49$) in Year 9 than those born with normal birth weight¹⁹. This is in line with findings at earlier time points, with the effect stronger for maths than for English and science.

Ethnicity

In Year 9 there is no statistically significant ethnicity effect on attainment in English, but in maths and science, students from Indian heritage obtained higher teacher assessment levels than other students (maths: $ES_{\text{Orig}}=0.37$; $ES_{\text{Imputed}}=0.32$; science: $ES_{\text{Orig}}=0.30$; $ES_{\text{Imputed}}=0.22^{\text{ns}}$).

¹⁹ Babies born weighing 2500 grams or less are defined as below normal birth weight: foetal infant classification is below 1000 grams, very low birth weight is classified as 1001-1500 grams and low birth weight is classified as 1501-2500 grams (Scott & Carran, 1989). In the present analyses, the categories foetal infant (<1000g) and very low birth weight (1001-1005g) were collapsed into one category due to small numbers in the former group.

Family Size

At earlier ages, students from larger families (with 3 or more siblings) showed statistically significantly lower attainment in English and maths but not in science. In Year 6 there were no statistically significant differences in terms of family size. In the present analysis, adolescents with 3 siblings or more obtained lower levels in both English and maths. The academic attainment in English for students with 3 or more siblings was lower with a quarter of a TA level than for the students with no siblings.

Early Developmental and Behavioural Problems

Students whose parents reported early developmental and behavioural problems at the beginning of the pre-school phase of the study still showed lower attainment both in English and maths in Year 9 compared to students where no early developmental or behavioural problems were reported.

Table 2.7: Factors with Statistically Significant ‘Net’ Effect on English Teacher Assessment Levels in Year 9

Factor	Effect Size Original Data	Effect Size Imputed Data	Description
Age	0.19	0.19	Older students perform better than younger.
Gender	0.46	0.41	Females obtain higher attainment than males.
Birth Weight	0.37	0.53	Students born with normal birth weight achieve higher academic attainment than those born with very low birth weight.
Early Developmental Problems	0.21	0.22	One or more early developmental problems are predictors for lower academic achievement.
Early Behavioural Problems	0.18	0.20	One or more behavioural problems are predictors for lower academic achievement.
Number of Siblings	0.31	0.25	Three siblings or more predict lower academic achievement.
Mother's Age	0.16	0.12	Students with older mothers have better academic attainment.
Mother's qualifications	0.61	0.49	Higher mother's qualification is predictor of better academic attainment.
Father's qualifications	0.36	0.27	Higher father's qualification is predictor of better academic attainment.
Year 9 FSM	0.30	0.30	Receiving of being eligible for FSM is a negative predictor for academic attainment.
Family Socio-Economic Status	0.29	0.30	Students from families with higher SES perform better.
Family income	0.40	0.30	Students from families with high income perform better.
School Level FSM	0.19	0.18	Students from schools with high percentage of young adults receiving FSM have lower attainment.
Early years HLE	0.29	0.36	Higher scores on Early Years HLE are associated with higher attainment.
KS1 HLE	0.24	0.19	Frequent outdoors activities are associated with higher achievement.
KS2 HLE	0.19	0.15	Moderate computing usage is better than frequent computer usage.

Table 2.8: Factors with Statistically Significant ‘Net’ Effect on Maths Teacher Assessment Levels in Year 9

Factor	Effect Size Original Data	Effect Size Imputed Data	Description
Age	0.15	0.15	Older students perform better than younger.
Birth Weight	0.40	0.59	Students born with normal birth weight achieve higher academic attainment than those born with very low birth weight.
Ethnicity	0.37	0.32	Indian heritage better attainment than White UK heritage.
Early Developmental Problems	0.16	0.21	One or more early developmental problems are predictors for lower academic achievement.
Early Behavioural Problems	0.18	0.22	One or more behavioural problems are predictors for lower academic achievement.
Number of Siblings	0.19	0.14	Three siblings or more predict lower academic achievement.
Mother's qualifications	0.50	0.48	Higher mother's qualification is predictor of better academic attainment.
Father's qualifications	0.37	0.20	Higher father's qualification is predictor of better academic attainment.
Year 9 FSM	0.31	0.31	Receiving of being eligible for FSM is a negative predictor for academic attainment.
Family Socio-Economic Status	0.36	0.53	Students from families with higher SES perform better.
Family income	0.21	0.21	Students from families with higher income perform better.
School Level FSM	0.20	0.17	Students from schools with high percentage of young adults receiving FSM have lower attainment.
Early years HLE	0.38	0.42	Higher scores on Early Years HLE are associated with higher attainment.
KS2 HLE	0.17	0.17	Moderate computing usage is better than frequent computer usage.

Table 2.9: Factors with Statistically Significant ‘Net’ Effect on Science Teacher Assessment Levels in Year 9

Factor	Effect Size Original Data	Effect Size Imputed Data	Description
Age	0.16	0.15	Older students perform better than younger.
Birth Weight	0.33 ^{ns} (0.35) ²⁰	0.48 (0.49)	Students born with normal birth weight achieve higher academic attainment than those born with very low birth weight.
Ethnicity	0.30	0.22 ^{ns}	Indian heritage better attainment than White UK heritage.
Early Developmental Problems	0.15	0.21	One or more early developmental problems are predictors for lower academic achievement.
Mother's Age	0.09	0.07 ^{ns}	Students with older mothers have better academic attainment.
Mother's qualifications	0.61	0.53	Higher mother's qualification is predictor of better academic attainment.
Father's qualifications	0.48	0.26	Higher father's qualification is predictor of better academic attainment.
Year 9 FSM	0.31	0.29	Receiving of being eligible for FSM is a negative predictor for academic attainment.
Family Socio-Economic Status	0.31	0.40	Students from families with higher SES perform better.
Family income	0.29 ²¹	0.18 ^{ns}	Students from families with high income perform better.
School Level FSM	0.22	0.20	Students from schools with high percentage of young adults receiving FSM have lower attainment.
Early years HLE	0.41	0.36	Higher scores on Early Years HLE are associated with higher attainment.
KS1 HLE	0.15	0.09 ^{ns}	Frequent outdoors activities are associated with higher achievement.
KS2 HLE	0.17	0.15	Moderate individual activities are better than frequent ones.

²⁰ Effect size in the contextualised model that does not control for Year 9 FSM status

²¹ Significant only in the contextualised model that does not control for Year 9 FSM status

2.3. Family Measures

Regarding the background characteristics we found the following family factors having a statistically significant net effect on attainment in English, maths and science: mother's age, parents' qualification levels, eligibility for FSM, family SES, family's salary and school level FSM. The relative strength of different factors is indicated by the effect sizes (ES).

Mother's age

Mother's age was found to be a positive predictor for attainment in English and science. Mother's age was not significantly related to the educational attainment in maths. The effect sizes were slightly stronger for English than for science (English: $ES_{\text{Orig}}=0.16$; science: $ES_{\text{Orig}}=0.09$) and the estimates did not reach significance on the imputed data for science.

Parent's Highest Qualification Level

Both mother's and father's education were tested in the contextualised models to examine their associations with academic outcomes. Mother's education, as measured by the highest level of qualification, continued to show a consistent pattern of strong and positive effects. The categories degree and higher degree showed the strongest positive influence (compared with the group that had no qualifications) for results in English, maths and science (English: $ES_{\text{Orig}}=0.61$; $ES_{\text{Imputed}}=0.49$; maths: $ES_{\text{Orig}}=0.50$; $ES_{\text{Imputed}}=0.48$; science: $ES_{\text{Orig}}=0.61$; $ES_{\text{Imputed}}=0.53$). Thus, students whose mothers have a degree or higher degree gain a half of a TA level in English and more than half of a TA level in maths and science when compared to students whose mothers have no qualification. See Figure 2.2, Figure 2.3, and Figure 2.4 for details on effect sizes for other qualification levels compared to no qualification.

Also important for students' academic attainment is the father's qualification. Having a father with a degree or a higher degree is statistically significantly associated with higher levels in the students' English, maths and science TA (English: $ES_{\text{Orig}}=0.36$; $ES_{\text{Imputed}}=0.27$; maths: $ES_{\text{Orig}}=0.37$; $ES_{\text{Imputed}}=0.20$; science: $ES_{\text{Orig}}=0.48$; $ES_{\text{Imputed}}=0.26$). It seems that both parents' qualifications are important for academic attainment in Year 9, but the mother's qualification level show a stronger link to students' attainment (see Table A.6.1-Table A.6.3 in Appendix 6 for further details on effect sizes for different predictors).

Figure 2.2: The Net Effect of Mother's Highest Qualification on English Teacher Assessment Levels in Year 9

Figure 2.3: The Net Effect of Mother's Highest Qualification on Maths Teacher Assessment Levels in Year 9

Figure 2.4: The Net Effect of Mother’s Highest Qualification on Science Teacher Assessment Levels in Year 9

Free School Meals (FSM)

FSM, a marker for low income, was a negative predictor of academic attainment in Year 9; students eligible or receiving FSM performed worse than students who were not eligible. The ES were similar for English, maths and science (English: $ES_{Orig}=0.30$; $ES_{Imputed}=0.30$; maths: $ES_{Orig}=0.31$; $ES_{Imputed}=0.31$; science: $ES_{Orig}=0.31$; $ES_{Imputed}=0.29$)²². Students eligible or receiving FSM lost a quarter of a TA level in English and almost a third of a TA level in science when compared to students with no FSM.

Income

In terms of household salary, the results indicate that students in households with incomes of more than £37,500 per annum have better levels in English TA than those whose parents have no salary ($ES_{Orig}=0.20$; $ES_{Imputed}=0.22$). Higher salaries than £67,500 per annum were associated with an increase of a third of a TA level in English when compared to no salaries. The effect sizes obtained for maths for the “£37,500 – £66,000” salary category were $ES_{Orig}=0.21$ and $ES_{Imputed}=0.21$. Students from families with salaries between £37,500 and £66,000 gained a quarter of a TA level in maths when compared to students from families with no salaries. For science, family income was statistically significant only when the Year 9 FSM was removed from the contextualised model (Salary higher than £67,500: $ES_{Orig}=0.29$; $ES_{Imputed}=0.18^{ns}$).

Family SES

Family SES was computed for different time points: entry into the study, KS1, KS2 and KS3. Even though each of these alternatives of family SES was a significant predictor of academic outcome,

²²Note that effects cannot be compared directly to effect sizes that have been reported for earlier time points, because for these analyses an improved imputed measure has been used.

the best and most robust predictor was the family SES collected at the entry time by interviewing the parents. Therefore, the contextualised models based on this predictor were reported.

When compared with the ‘professional non-manual’ category (representing the highest possible SES category), all the other categories predicted lower levels of TA in English and science. However, statistically significant lower attainment in English was found for students whose parents belong to the ‘skilled manual’ group ($ES_{\text{Orig}}=-0.29$; $ES_{\text{Imputed}}=-0.30$; see Figure 2.5). For maths, more groups were significantly different from the highest category: ‘skilled manual’ ‘semi-skilled’ and ‘unskilled’ (see Figure 2.6). Students whose parents were in any of these categories performed significantly worse than the comparison group. The educational attainment in science was significantly related to the following SES categories ‘skilled non manual’, ‘skilled manual’ and ‘semi-skilled’ (see Figure 2.7).

Figure 2.5: The Net Effect of Family SES on English Teacher Assessment Levels in Year 9

Figure 2.6: The Net Effect of Family SES on Maths Teacher Assessment Levels in Year 9

Figure 2.7: The Net Effect of Family SES on Science Teacher Assessment Levels in Year 9

Overall results revealed that students whose parents belong to the highest SES group - professional non-manual - continue to have significantly higher attainment levels, net of the influence of income and qualifications, although qualifications have stronger relationships with academic outcomes than income or family SES.

Early Years Home Learning Environment (Early Years HLE) Measures

Measures of home learning environment were obtained from parents' responses at three time points: entry at study, KS1 and KS2. The indicators of the HLE in Early years were based on the frequency of specific activities involving the child, as reported by parents when children were recruited to the study during the pre-school period (i.e., teaching the child the alphabet, playing with letters and numbers, library visits, reading to the child, teaching the child songs or nursery rhymes). These measures were combined to form an overall Early Years HLE index with scores that could vary between 0 (very low Early Years HLE) and 49 (very high Early Years HLE).

When the overall HLE index was tested, it was found that the overall quality of the Early Years HLE remains a powerful predictor of better academic attainment at age 14, in secondary school. For all three attainment outcomes, only the two highest HLE categories were statistically significant (e.g., 25-32 and 33-45). For the top HLE category, the following effect sizes were obtained - English: $ES_{\text{Orig}}=0.29$; $ES_{\text{Imputed}}=0.36$, maths: $ES_{\text{Orig}}=0.38$; $ES_{\text{Imputed}}=0.42$ and science: $ES_{\text{Orig}}=0.41$; $ES_{\text{Imputed}}=0.36$ 'net' of other individual student and family factors (see Figure 2.8, Figure 2.9 and Figure 2.10). These results suggest that the importance of the experiences related to the learning opportunities at home during the Early Years continues to remain high for later secondary school academic outcomes even at age 14.

Figure 2.8: The Net Effect of Early Years HLE on English Teacher Assessment Levels in Year 9

Figure 2.9: The Net Effect of Early Years HLE on Maths Teacher Assessment Levels in Year 9

Figure 2.10: The Net Effect of Early Years HLE on Science Teacher Assessment Levels in Year 9

Key Stage 1 Home Learning Environment (KS1 HLE)

As the learning environment at home during the pre-school period was shown to have a strong impact on children’s academic attainment during pre-school, parents were again surveyed during KS1 (age 6-7 years) about their interactions with their child at home via a parent questionnaire. They reported on activities such as the frequency of reading to/ with the child, taking the child out on educational visits, computing activities, sport activities, dance, etc. It should be noted that the KS1 HLE measures were collected by questionnaire survey rather than interview and thus the data may be slightly less reliable than the measure of Early Years HLE collected via face-to face-interviews.

The individual KS1 HLE measures have been aggregated to form four factors representing different parental activities during KS1: Home Computing, One-to-one Interaction, Expressive Play and Enrichment Outings (see Sammons et al., 2008a; 2008b). All four factors were tested in models that controlled for the individual student and family characteristics, but also for Early Years HLE. The latter remained the stronger predictor even when KS1 HLE measures were included.

For attainment in English and science, only the Enrichment Outings factor was statistically significant (English: $ES_{\text{Orig}}=0.24$; $ES_{\text{Imputed}}=0.19$; science: $ES_{\text{Orig}}=0.15$; $ES_{\text{Imputed}}=0.09^{\text{ns}}$). Both moderate and frequent outings during KS1 were associated with higher levels of TA in English in Year 9. Only moderate levels of outings during KS1 were associated with better outcome in science. None of the KS1 HLE factors were related to the Year 9 TA levels in maths.

These results are different from the ones obtained in Year 6, where the KS1 HLE One-to-one Interaction and Home Computing factors were significant predictors of attainment in English and maths. It is possible that certain learning activities (i.e., reading to a child, using the computer) from home during KS1 were more likely to influence the academic outcome during the same time period, rather than later outcome. However, the link with enrichment activities such as outings seems to have lasting effects on later academic attainment.

Key Stage 2 Home Learning Environment (KS2 HLE)

The home learning environment seems to be interestingly related to academic attainment, remaining an important predictor that needs to be continually investigated. At KS2 another questionnaire was sent to the parents who were asked to state their level of involvement in different learning activities at home. The parents reported on activities such as the frequency of internet usage, taking the child out to physical activities and educational visits, computing activities, teaching the child different subjects.

Five KS2 HLE factors were extracted from the individual items: Educational Computing, Parent-Child Learning Processes, Parent-Child Reading Activities, Individual Child Activities and Computer Games (see Appendix 5). These factors were tested with respect to their influence on academic attainment at the end of Year 9. The models controlled for Early Years HLE and the statistically significant KS1 HLE specific factors.

Two of the KS2 HLE factors seemed to be important for academic attainment in Year 9: Educational Computing and Individual Activities. Education Computing was positively associated with the TA levels in English and maths. However, only the moderate levels of computer usage were associated with higher attainment in English ($ES_{\text{Orig}}=0.19$; $ES_{\text{Imputed}}=0.15$) and maths ($ES_{\text{Orig}}=0.17$; $ES_{\text{Imputed}}=0.17$) in Year 9, probably because just an optimal level of home computing is good for academic attainment. For attainment in science, the student's Individual Activities factor was statistically significant ($ES_{\text{Orig}}=0.17$; $ES_{\text{Imputed}}=0.15$). Only the moderate levels of Individual Activities during KS2 were associated with higher levels of TA in science in Year 9.

2.4. Neighbourhood 'Influence'

So far we have shown that individual student and family characteristics together with home learning environment measured at different time points continue to be very important predictors of students' academic attainment at age 14. In this section, we analyse whether a broader context like the neighbourhood environment has any influences on students' attainment in Year 9. Therefore, to the full contextualised models predicting academic outcomes multiple measures of neighbourhood environment were added. These measures were available either from census statistics or from the National Pupil Data (NPD) and consisted of the Index of Multiple Deprivation (IMD), percentage of White British citizens in the neighbourhood, level of crime, level of employment, percentage of residents with limiting long-term illness, the Income Deprivation Affecting Children Index (IDACI) and neighbourhood safety. The indicators were tested individually after control for individual student, family and HLE factors to avoid potential collinearity issues (see Table 2.10 for the correlations between different measures). The continuous measures of neighbourhood disadvantage were centred to the grand mean.

Level of employment and the percentage of residents with limiting long-term illness were features of the neighbourhood that were not significant predictors of the academic attainment at age 14. However, the other characteristics mentioned above were found to be significant predictors of academic outcome in secondary school.

Table 2.10: Correlations Between Different Measures of Neighbourhood Disadvantage (Original Data)

Neighbourhood Characteristics		IMD 2004	% of White British	Crime	Employment	% Limiting Long Term Illness	IDACI

** . Correlation is significant at the 0.01 level (2-tailed).

Index of Multiple Deprivation (IMD)

The first of the neighbourhood disadvantage measurements, IMD is a nationwide index combining weighted measures or levels of: crime, barriers to housing, living environment, education and skills training, health deprivation and disability, employment and income. The greater the IMD score, the greater the level of neighbourhood deprivation. The index is divided into Local Authority (LA) and Super Output Areas (SOA), where SOAs are defined as areas smaller than wards, frequently nested in wards, and of broadly consistent population size. For the purposes of analysis, the 2004 IMD scores were assigned to each child on the basis of their pre-school home address (using postcode) being used to identify the appropriate SOA (for further details of the IMD see Noble et al., 2004; 2008).

Results indicated that students' academic outcomes (especially English and science TA levels) were predicted significant by neighbourhood disadvantage as measured by IMD scores although the

effect sizes were only small (see Table 2.11, Table 2.12 and Table 2.13). The higher the multiple deprivation index scores the lower the academic results in Year 9 (English: $ES_{\text{Orig}}=-0.17$; $ES_{\text{Imputed}}=-0.18$; science: $ES_{\text{Orig}}=-0.14$; $ES_{\text{Imputed}}=-0.15$). For maths, the IMD was significant only on the imputed data.

Percentage of White British

The percentage of White British citizens in the neighbourhood was also a significant and negative predictor of students' academic attainment. A higher percentage of residents who are White British in the neighbourhood was a significant predictor of lower academic TA results in English ($ES_{\text{Orig}}=-0.20$; $ES_{\text{Imputed}}=-0.15$), maths ($ES_{\text{Orig}}=-0.15$; $ES_{\text{Imputed}}=-0.08^{\text{ns}}$) and science ($ES_{\text{Orig}}=-0.18$; $ES_{\text{Imputed}}=-0.10^{\text{ns}}$) (see Table 2.14, Table 2.15 and Table 2.16).

Level of Crime

Similarly, the level of crime in a neighbourhood was a significant predictor of academic outcomes in Year 9. A neighbourhood characterised by a higher level of crime negatively influenced the academic attainment in English ($ES_{\text{Orig}}=-0.17$; $ES_{\text{Imputed}}=-0.12$) and science TA results ($ES_{\text{Orig}}=-0.14$; $ES_{\text{Imputed}}=-0.14$). The associations of crime levels with results in maths were statistically significant only for the imputed data ($ES_{\text{Orig}}=-0.08^{\text{ns}}$; $ES_{\text{Imputed}}=-0.10$) (see Table 2.18).

Income Deprivation Affecting Children Index

Income Deprivation Affecting Children Index (IDACI) represents the percentage of children in each SOA that live in families that are income deprived. The overall IMD does not include the IDACI as the children are already captured in the Income Deprivation Domain.

Similarly to results for the IMD, IDACI is a negative predictor of students' academic outcomes in Year 9 (see Table 2.20, Table 2.21 and Table 2.22). Children who had grown up in a neighbourhood characterised by economically deprived families tend to do worse academically in Year 9, after control for their own family characteristics including family SES and income. Thus, the effect sizes of IDACI for English TA levels are $ES_{\text{Orig}}=-0.16$ and $ES_{\text{Imputed}}=-0.14$, while for science TA these are $ES_{\text{Orig}}=-0.15$; $ES_{\text{Imputed}}=-0.14$). The associations of IDACI with results in maths are statistically significant only for the imputed data ($ES_{\text{Orig}}=-0.10^{\text{ns}}$; $ES_{\text{Imputed}}=-0.11$).

Neighbourhood Safety

The indicator of neighbourhood safety was based on parents' own perceptions derived from the KS1 parent questionnaire. The results of the relationships between the views on neighbourhood safety and students' later academic outcome are presented in Table 2.23 and Table 2.24. These findings indicated that only for maths and science, a high level of neighbourhood safety was a significant predictor of higher academic TA levels, when compared to low safety (maths: $ES_{\text{Orig}}=0.13$; $ES_{\text{Imputed}}=0.13^{\text{ns}}$; science: $ES_{\text{Orig}}=0.18$; $ES_{\text{Imputed}}=0.17$). English TA results in Year 9 were not significantly related to the level of neighbourhood safety.

Overall, it was found that specific features of the neighbourhood where children lived while at pre-school age continue to have influence on their academic outcomes in secondary school. It seems that some of these influences are stronger in Year 9 than in Year 6 (where for example, IMD scores failed to reach significant levels in influencing English and maths KS2 National Assessment test scores). This could be attributed to the fact that teachers might be more likely 'biased' by the students' family and broader social context when assessing their academic results (Gibbons & Chevalier, 2008; Harlen, 2005). Evidence of biases captured by the TA levels was also found in previous analyses for cohort 1 and 2 (see Sammons et al., 2009). These analyses showed the TA levels accentuated existing social disparities when controlling for actual test performance. More concrete, TA levels exaggerated the advantage of girls in English, the underachievement of young people with prior behaviour problems and the underachievement of the young people from poorer families as compared with those from high income families.

Previous research has indicated the control for neighbourhood disadvantage is essential as this variable proved to be a significant predictor of attainment and progress in English National

Assessment test scores. Such measures (e.g., IMD) were also included in the DfE CVA models to control for the possible influences of the neighbourhood in evaluating school outcome.

These data also confirm that neighbourhood effects are statistically significant in shaping KS3 results. In primary school the EPPE research found that neighbourhood measures were not statistically significant predictors of children's attainment when the early influence of home learning was taken into account. However, even when Early Years HLE was controlled in these models, it was shown that neighbourhood disadvantage was a significant predictor, although relatively weak, for the same students at age 14. This suggests that the neighbourhood context became more important in shaping students' educational outcomes as they grow older and this is likely to reflect students' greater involvement in activities outside the home and with their peer group in the local area as they move into early adolescence.

3. Students' Academic Attainment at the End of Year 9 in Secondary School: The Impact of Pre-school, Primary and Secondary School

The contextualised models presented in the previous section emphasised the importance of the individual student and family background as well as the specific characteristics of the immediate social context in shaping students' academic attainment in Year 9. We have clear evidence that the range of individual student, parent and HLE factors continue to show a both statistically and educationally significant relationship with academic outcomes in Year 9, echoing earlier outcomes at the end of primary school or at the end of Year 2. The pattern of findings is in line with other studies about academic achievement in secondary schools (Sammons, 1995).

In order to further investigate whether there are any continuing effects of pre-school attendance, quality or effectiveness on later academic attainment, it is important to take into account the individual background. Similar control is needed when examining the potential impact of primary or secondary school effectiveness on academic results. One of the most important findings of the EPPE study was that the experiences in various pre-school centres had a statistically significant effect on academic attainment measured at different time points, up to age 11. The consistency and the persistence of the pre-school effects on academic attainment over the time lead to an important aim of the Year 9 analyses, which was to establish whether there is evidence of any continuing pre-school influence in secondary school at age of 14 years. Additionally, we were interested whether primary school has an influential impact on students' academic attainment and progress in secondary school. Similarly, we expect that the characteristics of secondary school attended could possibly influence the level of students' attainment. Another aim is to investigate the combined influences of pre-, primary and secondary school on young students' academic attainment in Year 9.

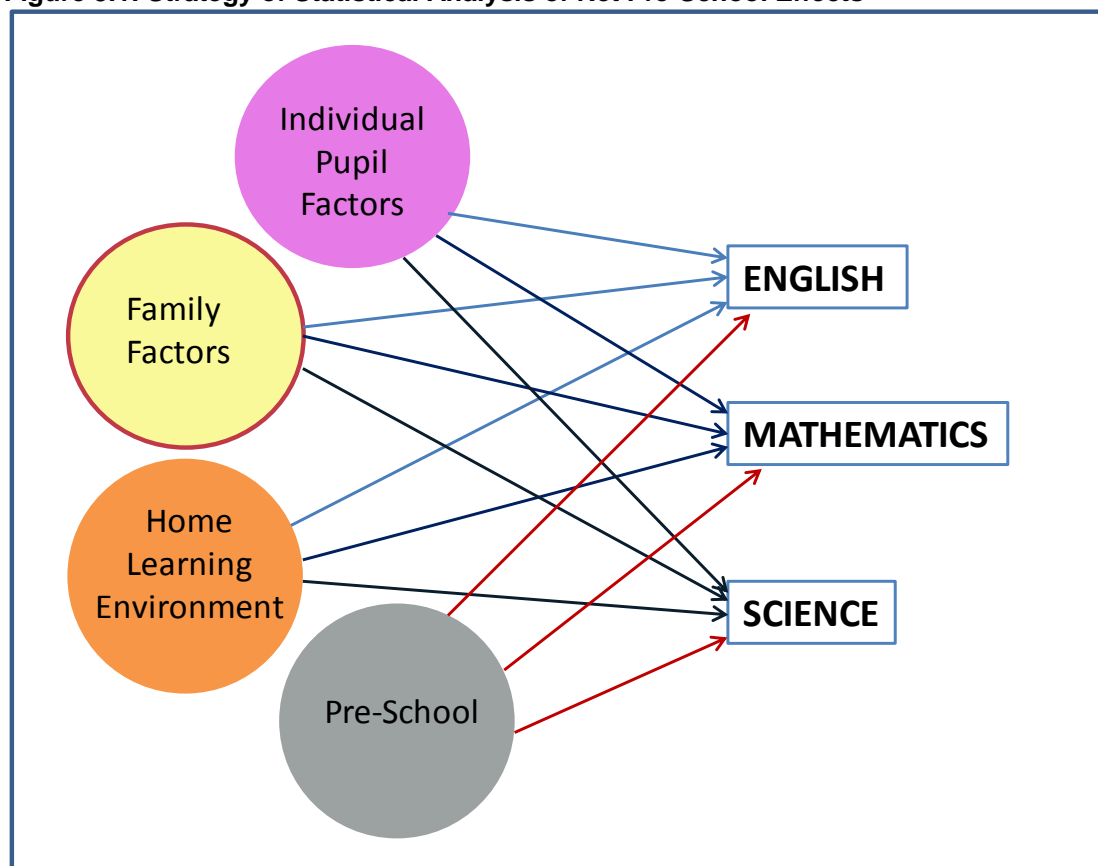

A further major interest of the analyses was to explore whether the pre-school experience, primary and secondary school effectiveness have different influences on different groups of students such as students of less qualified parents or with different levels of the HLE (the concept of differential effects or benefits).

This section presents results of contextualized multilevel modelling analyses that have been used to investigate the described research questions.

3.1. The Impact of Pre-school Experience on Year 9 Attainment

Three aspects of pre-school experience were considered to investigate any continuing effect on Year 9 academic attainment: attendance at a pre-school centre compared to no pre-school, pre-school quality and pre-school effectiveness. Also, the combined impact of Early Years HLE and pre-school experience was investigated (see Figure 3.1 for an illustration of the analysis strategy). The findings from these complex analyses focus on the presentation of effect sizes.

Figure 3.1: Strategy of Statistical Analysis of Net Pre-School Effects

3.1.1. The Continuing Impact of Pre-School Attendance at Later KS3 Attainment

There is no evidence of continuing pre-school attendance or pre-school quality effects on students' later English attainment levels as measured by TA levels.

The most basic indicator of the pre-school experiences proved to be significantly associated with attainment in maths and science, after controlling for individual and family characteristics, Early Years HLE, KS1 and KS2 HLE. The effect sizes are presented in Table 3.1 and Table 3.2.

Attending a pre-school continues to have a positive relationship with maths ($ES_{\text{Orig}}=0.26$; $ES_{\text{Imputed}}=0.25$) and science TA levels ($ES_{\text{Orig}}=0.22$; $ES_{\text{Imputed}}=0.22$). The same effect size of pre-school attendance was found for maths test scores in Year 6 ($ES=0.26$; Sammons, 2008a).

3.1.2. The Continuing Impact of Pre-school Centre Quality at Later KS3 Attainment

Pre-school quality was measured with two different scales: ECERS-R and ECERS-E (Sylva et al., 1999; 2006). Previous report had found that ECERS-E, which focuses on the education aspects of pre-school, had the most consistent effects upon academic attainment. The original sample was divided into groups of students whose pre-school experience could be classified as ranging from no quality (i.e., the 'home' group) through low, medium and high quality, based on individual pre-school centres' ECERS-E scores. The distribution of ECERS-E groups in the present sample was the following: no pre-school (10%) low quality (14%), medium quality (54%) and high quality (22%).

As with earlier time points showed a positive impact of higher quality pre-school provision on academic outcomes, the results from Year 9 indicated that the "home" group significantly differed in their academic attainment from students attending medium or high quality pre-school settings. For the attainment in maths, even a lower quality setting was better than no-pre-school ($ES_{\text{Orig}}=0.22$; $ES_{\text{Imputed}}=0.20$). Additionally, the better the pre-school's quality the higher the students' later outcomes measured by KS3 TA levels in maths (see Table 3.3).

In terms of attainment in science, only the experience of medium and high quality pre-school provision showed a statistically significant positive impact at the end of Year 9 when compared to the experience of staying at home. The ES for both types of provision were very similar (Medium quality: $ES_{\text{Orig}}=0.23$; $ES_{\text{Imputed}}=0.23$; High quality: $ES_{\text{Orig}}=0.22$; $ES_{\text{Imputed}}=0.23$) (see Table 3.4).

Table 3.3: Contextualised Models for Maths Teacher Assessment Levels in Year 9: Pre-school Quality Measured by ECERS-E (Original Data vs. Imputed Data)

% Reduction total variance	34%				26%			

* $p < 0.05$

We can conclude that for both maths and science attending a medium to high quality pre-school was associated with significantly enhanced attainment compared to no pre-school, but in contrast to findings in primary school, there were no longer significant differences in English results at age 14.

3.1.3. The Continuing Impact of Pre-school Centre Effectiveness at Later KS3 Attainment

Measures of pre-school centre effectiveness were calculated separately for Pre-Reading and Early Number Concepts for all pre-school centres in the study. These measures were the residuals from multilevel value added models predicting academic attainment (at the end of pre-school) of students who attended a pre-school centre, controlling for their prior attainment at entry to the study and background influences. Pre-schools where children made more progress than predicted were more effective than those where children made less progress than predicted (on basis of prior attainment and background characteristics) (Sammons et al., 2002). Measures of pre-school centre effectiveness proved to be significant predictors of students' subsequent academic attainment in primary school. Therefore, it was expected that these effects might continue to shape students' attainment later on in KS3 as well. In order to establish whether the effectiveness of the pre-school setting attended showed any continuing impact on the attainment at KS3, further multilevel analyses were conducted on the Year 9 English, maths and science outcomes. In these analyses, pre-school centre effectiveness in promoting young children's progress in Pre-Reading was tested as a potential predictor for English attainment in Year 9. Pre-school centre effectiveness, in terms of

promoting young children's progress in Early Number Concepts, was tested as a predictor for later maths and science attainment in Year 9.

Table 3.5, Table 3.6 and Table 3.7 show that after controlling for individual student, family and HLE influences, the measures of centre effectiveness still showed a statistically significant positive 'net' impact on students' attainment in English, maths and science at Year 9.

Regarding the Year 9 English attainment, students who had previously attended a highly effective pre-school continued to show a benefit in terms of significantly higher attainment than students who had not attended any pre-school ($ES_{\text{Orig}}=0.20$; $ES_{\text{Imputed}}=0.16^{\text{ns}}$).

Table 3.5: Contextualised Models for English Teacher Assessment Levels in Year 9: Pre-school Effectiveness (Pre-Reading) (Original Data vs. Imputed Data)

	Year 9 English TA Original Data				Year 9 English TA Imputed Data STATA ICE

Pre-school Effectiveness Pre-reading (compared to no pre-school)								
Low effectiveness	0.06	0.08	0.07		0.07	0.08	0.08	
Medium effectiveness	0.14	0.07	0.17		0.09	0.08	0.11	
High effectiveness	0.16	0.08	0.20	*	0.14	0.08	0.16	
% Reduction school variance	81%				70%			
% Reduction student variance	24%				16%			
% Reduction total variance	38%				30%			

* $p < 0.05$

The three categories of pre-school effectiveness predicted better attainment in maths; students who went to low, medium or high effective pre-schools had significantly higher TA levels than students who had not attended a pre-school (see Table 3.6). However, there was no clear trend differentiating low and high effective pre-schools.

Table 3.6: Contextualised Models for Maths Teacher Assessment Levels in Year 9: Pre-school Effectiveness (Early Number Concepts) (Original Data vs. Imputed Data)

% Reduction total variance	30%				26%			

* $p < 0.05$

Similarly, students who went to medium or high effective pre-schools (in terms of early number concepts) had significantly higher attainment in science TA levels in Year 9 than those who had not attended a pre-school (see Table 3.7). Here there was a trend indicating that only a medium or a high effective pre-school (in terms of promoting early number concepts) predicted better outcomes. The ES for high effective pre-school was similar in size to the FSM measure in science.

3.1.4. Different Pre-school Effects for Different Groups of Students

A topic of particular interest is whether pre-school experience has different effects on particular groups of students, specifically those more vulnerable to risk of low attainment. In terms of risk, key features were identified as having considerable impact on attainment: the students' Early Years HLE and the level of their parents' highest qualification. Each of these was considered in relation to pre-school attendance, pre-school quality, and pre-school effectiveness.

The Combined Impact of Pre-school Experience and Early Years Home Learning Environment (HLE)

Given that the described analyses have already demonstrated modest effects for the quality and effectiveness of pre-school experience but strong effects for the Early Years HLE on later academic attainment, their joint effects were investigated. For this analysis, the Early Years HLE index was regrouped into three categories representing low, medium and high Early Years HLE. Next, combined terms were created between Early Years HLE and pre-school attendance, pre-school quality (measured by ECERS-E) and pre-school effectiveness. These joint measures were then entered in the contextualised models that controlled for individual and family characteristics.

Early Years HLE and Pre-school Attendance

Table 3.8 shows the combined effects of Early Years HLE and pre-school attendance (yes/no) on the original and imputed English TA levels in Year 9. The reference group for these analyses was the group of students with no pre-school and low Early Years HLE.

Figure 3.2 shows, for English, the positive effect of a medium and high quality Early Years HLE for the 'home' group. Students with no pre-school but who scored high on the Early Years HLE index showed higher levels of attainment in English ($ES_{\text{Orig}}=0.48$; $ES_{\text{Imputed}}=0.42$) than students with no pre-school but with low Early Years HLE.

However, attending a pre-school was especially beneficial for those who did not experience a good Early Years HLE. These students performed significantly better than those with similar low levels of HLE but no pre-school ($ES_{\text{Orig}}=0.37$; $ES_{\text{Imputed}}=0.29$). The greatest advantage in later English attainment was for the students who had attended a pre-school and also had high Early Years HLE ($ES_{\text{Orig}}=0.57$; $ES_{\text{Imputed}}=0.49$).

Table 3.8: Contextualised Models for English Teacher Assessment Levels in Year 9: Early Years HLE by Pre-school Attendance Combined Term (Original Data vs. Imputed Data)

% Reduction total variance	32%				29%			

* $p < 0.05$

Figure 3.2: The Combined Impact of Early Years HLE and Pre-school Attendance on English Teacher Assessment Levels in Year 9

For maths and science the pattern of results differed slightly from the results in English (see Table 3.9 and Table 3.10). Figure 3.3 and Figure 3.4 illustrate that the Early Years HLE in combination with pre-school attendance had a strong positive influence on maths and science TA levels in Year 9, when controlling for other background factors such as family SES or qualification of parents, although the effects were largely driven by HLE.

Later attainment in maths and science improved significantly for students with a low Early Years HLE who had attended a pre-school (maths: $ES_{\text{Orig}}=0.56$; $ES_{\text{Imputed}}=0.46$; science: $ES_{\text{Orig}}=0.48$; $ES_{\text{Imputed}}=0.40$). Pre-school attendance did not continue to make a difference for Year 9 attainment when students experienced a medium Early Years HLE (see Figure 3.3 and Figure 3.4). Nevertheless, the advantage of a high Early Years HLE was increased even more by pre-school attendance (maths: $ES_{\text{Orig}}=0.74$; $ES_{\text{Imputed}}=0.65$; science: $ES_{\text{Orig}}=0.71$; $ES_{\text{Imputed}}=0.61$).

Taken together the results support the view that students with low Early Years HLE but who had previously attended a pre-school got better results in Year 9 than those with similar level of HLE and no pre-school, when controlling for all other individual and family factors. The continued impact of pre-school for medium Early Years HLE was insignificant, and for high Early Years HLE, the pre-school effect was only weak but statistically significant.

Figure 3.4: The Combined Impact of Early Years HLE and Pre-school Attendance on Science Teacher Assessment Levels in Year 9

Early Years HLE and the Quality of the Pre-school

As previous analyses showed the effects of pre-school remain evident in Year 9 even when considering just simple attendance. Further analyses were conducted to investigate whether the quality of the pre-school combined with Early Years HLE predicts significantly the later attainment in Year 9. The results gives us further insight into the way Early Years HLE and pre-school may interact in influencing students' academic attainment in the longer term. Similarly to the previous analyses, the reference group was the 'no pre-school and low Early Years HLE' group. Results for English, maths and science TA levels were reported in terms of effect sizes (see Table 3.11-Table 3.13).

Figure 3.5 shows the results for English TA levels and indicates that students with low Early Years HLE gained similar advantages from attending pre-school regardless of quality (ES_{Orig} between 0.33-0.43; $ES_{Imputed}$ between 0.25-0.36). Pre-school attendance did not improve the later attainment for those with medium level of Early Years HLE (when compared within the HLE group). Also students with medium Early Years HLE performed similarly regardless of pre-school and worse than those who had not attended a pre-school (Medium HLE and No pre-school: $ES_{Orig}=0.57$; $ES_{Imputed}=0.33^{ns}$).

High Early Years HLE combined with medium or high quality pre-schools were found to have the strongest positive long term benefits in English TA at the end of Year 9 (Medium Quality: $ES_{Orig}=0.61$; $ES_{Imputed}=0.52$; High Quality: $ES_{Orig}=0.55$; $ES_{Imputed}=0.47$). The students who had not attended any pre-school benefited from having a high Early Years HLE ($ES_{Orig}=0.49$; $ES_{Imputed}=0.42$). However, this effect was not as large as the one found for students with medium Early Years HLE ($ES_{Orig}=0.57$; $ES_{Imputed}=0.33^{ns}$). For students who had attended a low quality pre-school, those with high Early Years HLE ($ES_{Orig}=0.45$; $ES_{Imputed}=0.36$) were doing better in terms of English TA levels than those with medium Early Years HLE ($ES_{Orig}=0.27^{ns}$; $ES_{Imputed}=0.22^{ns}$).

These results show similar patterns as the ones found for English National Assessment test scores in Year 6 (see Sammons et al., 2008a) underlining the fact that the quality of Early Years HLE continues to remain important in predicting English attainment in Year 9. However, the impact of the quality of pre-school experience is no longer clearly discerned, the main long-term difference appears to be related to attending pre-school for low HLE students.

Figure 3.5: The Combined Impact of Early Years HLE and Pre-school Quality (ECERS-E) on English Teacher Assessment Levels in Year 9

Figure 3.6 shows that pre-school quality together with Early Years HLE had positive effects for maths TA levels in Year 9. Students with low Early Years HLE obtained better results if they had previously attended a high quality pre-school ($ES_{\text{Orig}}=0.66$; $ES_{\text{Imputed}}=0.56$) when compared to ‘no pre-school and low HLE’. As shown for English, students with medium Early Years HLE had similar levels of attainment in maths regardless of the pre-school’s quality. However, students with medium Early Years HLE who had not attended pre-school performed significantly better than students who stayed at home and experienced low Early Years HLE ($ES_{\text{Orig}}=0.55$; $ES_{\text{Imputed}}=0.40$).

In contrast, high Early Years HLE students gained greater benefits from attending a medium and high quality pre-school for later maths results (Medium Quality: $ES_{\text{Orig}}=0.79$; $ES_{\text{Imputed}}=0.68$; High Quality: $ES_{\text{Orig}}=0.68$; $ES_{\text{Imputed}}=0.62$) than students with low Early Years HLE and no pre-school. The impact of the medium quality pre-school was larger for students with high Early Years HLE ($ES_{\text{Orig}}=0.79$; $ES_{\text{Imputed}}=0.68$) than for students with low Early Years HLE ($ES_{\text{Orig}}=0.51$; $ES_{\text{Imputed}}=0.43$).

The results for the joint terms indicated that the benefits of pre-school-experience were mediated by the quality of Early Years HLE experienced by students.

Figure 3.6: The Combined Impact of Early Years HLE and Pre-school Quality (ECERS-E) on Maths Teacher Assessment Levels in Year 9

The pattern of results for science was similar to that for Maths (see Figure 3.7). The medium and high quality pre-school gave the biggest boost to those who had a high Early Years HLE (Medium Quality: $ES_{\text{Orig}}=0.77$; $ES_{\text{Imputed}}=0.66$; High Quality: $ES_{\text{Orig}}=0.64$; $ES_{\text{Imputed}}=0.57$). Attending a high quality pre-school lead to better results in science even for those with low ($ES_{\text{Orig}}=0.55$; $ES_{\text{Imputed}}=0.46$) and medium Early Years HLE ($ES_{\text{Orig}}=0.60$; $ES_{\text{Imputed}}=0.48$) when compared to 'no pre-school and low HLE'.

These results suggest that pre-school and the home learning environment have long lasting impact on later attainment.

Figure 3.7: The Combined Impact of Early Years HLE and Pre-school Quality (ECERS-E) on Science Teacher Assessment Levels in Year 9

Early Years HLE and Pre-school Effectiveness

Further analyses focused on the combined term between Early Years HLE and pre-school centre effectiveness. Based on previous results, we expected to find differentiated effects of Early Years HLE and pre-school centre effectiveness on Year 9 attainment measured by English, maths and science TA levels.

Overall, the results show that compared with the “low HLE and no pre-school group” those who had attended pre-school had better outcomes. However, the results did not indicate better outcomes in KS3 English for those students who had attended more effective pre-schools.

Figure 3.8: The Combined Impact of Early Years HLE and Pre-school Effectiveness (Pre-reading) on English Teacher Assessment Levels in Year 9

For Maths, high pre-school effectiveness combined with high Early Years HLE had a large effect size ($ES_{\text{Orig}}=0.92$; $ES_{\text{Imputed}}=0.79$), when compared to the students from the 'no pre-school and low HLE' group (see Figure 3.9). Students who had a low Early Years HLE showed more advantage if they had previously attended pre-schools that were highly effective in promoting students' progress in early number concepts ($ES_{\text{Orig}}=0.65$; $ES_{\text{Imputed}}=0.55$), as opposed to medium ($ES_{\text{Orig}}=0.53$; $ES_{\text{Imputed}}=0.43$) or low effective pre-schools ($ES_{\text{Orig}}=0.57$; $ES_{\text{Imputed}}=0.49$).

Figure 3.9: The Combined Impact of Early Years HLE and Pre-school Effectiveness (Early Number Concepts) on Maths Teacher Assessment Levels in Year 9

Strong joint effects of Early Years HLE combined with pre-school effectiveness were also obtained for Science. In the low Early Years HLE group, the ES increased with pre-school effectiveness (see Figure 3.10), in contrast to the patterns found for English. The highest effect size in this group was obtained by the students who had attended a highly effective pre-school when compared to those who had not attended any pre-school and had low Early Years HLE ($ES_{\text{Orig}}=0.61$; $ES_{\text{Imputed}}=0.50$). Similar gradation in attainment was found for students with medium Early Years HLE. However, it

has to be noted that only the students who had attended highly effective pre-schools performed better than the students who had not attended a pre-school with medium level of Early Years HLE. The most advantaged students were again those who had attended a highly effective pre-school and had a high Early Years HLE ($ES_{\text{Orig}}=0.85$; $ES_{\text{Imputed}}=0.70$).

Figure 3.10: The Combined Impact of Early Years HLE and Pre-school Effectiveness (Early Number Concepts) on Science Teacher Assessment Levels in Year 9

Parents' Qualification Level and the Impact of Pre-school Experience

Using the highest qualification of the parents, we divided the sample into two groups: lower versus more qualified parents. The parents who had 'no qualification', 'vocational' or '16 academic' were categorised as lower qualified. Thus, if both of the parents were in any of these 3 groups the *Parent's highest qualification* variable was set to lower qualified. Conversely, if at least one of the parents had a qualification higher than '16 academic' then the *Parent's highest qualification* variable was set as moderate/high. Joint measures were created between parents' highest qualification and pre-school attendance, pre-school quality and pre-school effectiveness. The combined terms were then entered into the contextualised models predicting academic attainment (English, maths and science TA levels) in Year 9 and controlling for individual and family characteristics.

With regard to the effect of past pre-school attendance, pre-school continues to be a statistically significant predictor for later attainment in Year 9. This is the case for the attainment in English but only for students of highly qualified parents ($ES_{\text{Orig}}=0.55$; $ES_{\text{Imputed}}=0.43$). However, for maths and science TA levels, pre-school attendance had a statistically significant effect for students of both low and highly qualified parents (see Table 3.18 and Table 3.19).

Figure 3.13: The Combined Impact of Parents' Highest Qualification and Pre-school Attendance on Science Teacher Assessment Levels in Year 9

Parents' Qualification Level and Pre-school Quality and Effectiveness

For English, both pre-school quality and pre-school effectiveness were statistically significant only for students of higher qualified parents (see Figure 3.14 and Figure 3.17). Within this specific group, the pre-school effects were similar regardless of the quality. These results reinforce the fact that parents' qualification remained a strong predictor of better English attainment in the long term. For English, therefore parents' qualification remains important, however it seems that there remains an extra benefit from having attended pre-school, although there is no clear trend linked to quality, in contrast to findings in primary school.

Figure 3.14: The Combined Impact of Parents' Highest Qualification and Pre-school Quality (ECERS-E) on English Teacher Assessment Levels in Year 9

In contrast to results for English, the results for maths and science indicated that attainment in these subjects were sensitive to pre-school quality (see Figure 3.15). Medium and high quality pre-school benefited students of parents with lower qualification (Medium quality: $ES_{\text{Orig}}=0.29$; $ES_{\text{Imputed}}=0.25$; High quality: $ES_{\text{Orig}}=0.30$; $ES_{\text{Imputed}}=0.26$). On the other hand, students of higher qualified parents, regardless of the attended pre-school's quality, had significantly greater attainment in maths than the 'home' students with lower qualified parents. However, students of higher qualified parents who had not attended pre-school showed lower outcomes than those who had attended pre-school.

The pattern was similar for science (see Table 3.22 and Figure 3.16). Students of higher qualified parents who had attended low quality pre-school differed substantially ($ES_{\text{Orig}}=0.60$; $ES_{\text{Imputed}}=0.53$) from those who had not attended pre-school and were of lower qualified parents. This was also the case for those who had attended medium quality pre-schools: students with low qualified parents had lower attainment ($ES_{\text{Orig}}=0.23$; $ES_{\text{Imputed}}=0.23$) than those of highly qualified parents ($ES_{\text{Orig}}=0.66$; $ES_{\text{Imputed}}=0.56$).

In summary, students of lower qualified parents seem to be more sensitive to benefits of the quality of the pre-school attended, the higher the quality the better their academic outcome in Year 9, in maths and science, although the differences are small. For the students of moderately to highly qualified parents there was no clear pattern of the effects related to pre-school quality.

Figure 3.16: The Combined Impact of Parents' Highest Qualification and Pre-school Quality (ECERS-E) on Science Teacher Assessment Levels in Year 9

The combined effect of parents' qualifications and pre-school effectiveness displayed similar patterns as the combined effect of parents' qualifications and pre-school quality. For English, pre-school effectiveness influenced outcomes only for the students of higher qualified parents. Thus, students from this group, regardless of pre-school effectiveness, had significantly greater attainment than students from the lower qualified/no pre-school group (see Figure 3.17). Differences in attainment based on pre-school effectiveness for students of lower qualified parents were not statistically significant from those who had not attended a pre-school, although the effect sizes were in the direction predicted.

Figure 3.17: The Combined Impact of Parents' Highest Qualification and Pre-school Effectiveness (Pre-reading) on English Teacher Assessment Levels in Year 9

Pre-school effectiveness was found to be more influential for Year 9 maths and science. Thus, the differences based on the pre-school effectiveness were statistically significant for both the 'lower' and 'higher qualified parents' categories when compared to students who had not attended a pre-school. As with pre-school quality, for students of higher qualified parents, pre-school effectiveness predicted Year 9 outcomes in the direction expected, and with greater attainment than 'home' students with lower qualified parents.

Compared to 'home' students with lower qualified parents, students with lower qualified parents who had attended low effective pre-schools had lower attainment in maths ($ES_{\text{Orig}}=0.31$; $ES_{\text{Imputed}}=0.25$) and science (although not significant, $ES_{\text{Orig}}=0.17^{\text{ns}}$; $ES_{\text{Imputed}}=0.17^{\text{ns}}$) than students with higher qualified parents who had attended low effective pre-schools (maths: $ES_{\text{Orig}}=0.65$; $ES_{\text{Imputed}}=0.56$; science: $ES_{\text{Orig}}=0.56$; $ES_{\text{Imputed}}=0.46$). Similar differences in attainment were found for those who attended a pre-school with medium level of effectiveness: students with lower qualified parents had lower attainment (maths: $ES_{\text{Orig}}=0.24$; $ES_{\text{Imputed}}=0.19$; science: $ES_{\text{Orig}}=0.20$; $ES_{\text{Imputed}}=0.20$) than those with higher qualified parents (maths: $ES_{\text{Orig}}=0.64$; $ES_{\text{Imputed}}=0.52$; science: $ES_{\text{Orig}}=0.64$; $ES_{\text{Imputed}}=0.56$). Finally, the same pattern of differences was found for students with lower qualified parents who attended high effective pre-schools (maths: $ES_{\text{Orig}}=0.38$; $ES_{\text{Imputed}}=0.34$; science: $ES_{\text{Orig}}=0.40$; $ES_{\text{Imputed}}=0.38$) and students with higher qualified parents who attended high effectiveness pre-schools (maths: $ES_{\text{Orig}}=0.71$; $ES_{\text{Imputed}}=0.57$; science: $ES_{\text{Orig}}=0.60$; $ES_{\text{Imputed}}=0.49$).

For Year 9 attainment in maths and science, students of lower qualified parents benefited more from highly and medium effective pre-school, but not particularly from low effective pre-schools. This suggests that pre-school effects still shape students' attainment in the longer term into lower secondary education.

Figure 3.19: The Combined Impact of Parents' Highest Qualification and Pre-school Effectiveness (Early Number Concepts) on Science Teacher Assessment Levels in Year 9

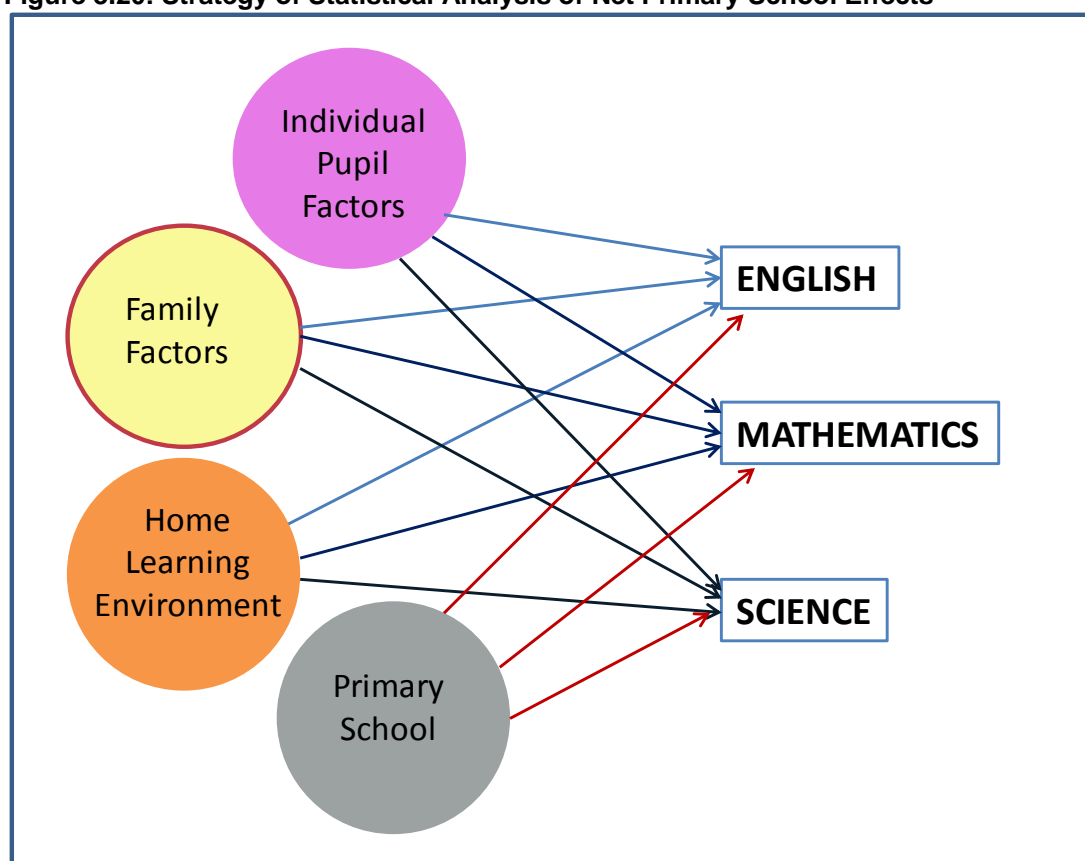

3.2. The Impact of Primary School Academic Effectiveness on Year 9 Attainment

Earlier in the study, measures of the academic effectiveness of the primary school attended had been derived. The value added effectiveness measures for primary schools were calculated using National Assessment data for all primary schools in England linking KS1 and KS2 results, and separate indicators were calculated for the different core curriculum subjects English, maths and science (Melhuish et al., 2006a; 2006b). These provided a measure of the academic success of individual primary school in promoting students' academic progress. For each EPPSE student, these measures provide indicators of the academic quality of their primary schools.

It was hypothesised that primary school might also continue to affect later attainment up to Year 9²³. To test this hypothesis, effectiveness measures of primary school academic effectiveness were incorporated in multilevel models to explore the influence of the primary school attended on promoting academic attainment in Year 9. Primary school academic effectiveness in English was modelled as a potential predictor for students' English outcomes in Year 9, and primary school academic effectiveness in maths was used as a potential predictor for outcomes in maths and science, while the primary school academic effectiveness in science was also tested as a predictor for the Year 9 science (see Figure 3.20 for the statistical analysis strategy).

Figure 3.20: Strategy of Statistical Analysis of Net Primary School Effects

²³ It was not appropriate to use cross classified models to examine the effects of primary and secondary school simultaneously as there were too many cells in the cross classification with one individual student

The academic effectiveness of the primary school had been found to predict outcomes in Year 5 and Year 6 (Sammons et al., 2007a; 2008a).

The primary school academic effectiveness was not statistically significant for the Year 9 attainment in English measured by TA levels. However, the academic effectiveness of the primary school attended remained a significant predictor of students’ attainment in Year 9 maths and science. The primary school makes an identifiable and separate contribution to students’ later attainment at Year 9 in these two subjects, after controlling for individual student, family and HLE influences.

Figure 3.21: The Impact of Primary School Academic Effectiveness on Maths and Science Teacher Assessment Levels in Year 9

Students who had attended a highly or medium effective primary school in terms of maths had significantly higher maths TA levels (Medium: $ES_{Orig}=0.13$; $ES_{Imputed}=0.11^{ns}$; High: $ES_{Orig}=0.31$; $ES_{Imputed}=0.28$) than students who had attended a low effective primary school. For Science, only attending a highly effective primary school was a significant predictor of higher TA levels ($ES_{Orig}=0.29$; $ES_{Imputed}=0.27$). Additionally, the primary school academic effectiveness in maths was a better predictor for science than primary school academic effectiveness in science (see Table 3.27 and Table 3.28).

Influences of Primary School Academic Effectiveness for Different Groups of Students

In this part of the report, the analyses explored differential influences of primary school academic effectiveness on students' academic attainment at Year 9. The combined term between parents' highest qualification and the academic effectiveness of the primary school attended were entered into multilevel models after controlling for individual student, family (excluding the parents' qualifications) and HLE measures. Due to the fact that forming multiple groups reduces the number of students in each group, we grouped the medium and highly effective primary schools together.

Parents' Qualification Level and the Impact of Primary School Academic Effectiveness

For these analyses, we used the *Parent's highest qualification* variable described previously. As we did not find an overall effect of the primary school academic effectiveness for the later attainment in English, the combined term between effectiveness and parents' qualification was only explored for maths and science outcomes.

For later attainment in maths, the primary school academic effectiveness was important for those of lower qualified parents. Compared to students who had attended low effective primary schools, students who had attended a highly ($ES_{\text{Orig}}=0.33$; $ES_{\text{Imputed}}=0.34$) or medium academically effective ($ES_{\text{Orig}}=0.16$; $ES_{\text{Imputed}}=0.18$) primary school have significantly higher maths TA levels in Year 9.

The relative effectiveness of the primary school was also important for students of parents with higher qualifications with effect sizes ranging from 0.47 to 0.64 (see Figure 3.22). The biggest benefit in increasing later academic outcome was experienced by the students who had attended a highly effective primary school.

Figure 3.22: The Combined Impact of Parents' Highest Qualification and Primary School Academic Effectiveness on Maths Teacher Assessment Levels in Year 9

The results for attainment in science followed a similar pattern (see Figure 3.23). TA levels in science were greater for students whose parents had a higher qualification and had attended a highly effective primary school ($ES_{\text{Orig}}=0.34$; $ES_{\text{Imputed}}=0.30$). The differences in attainment between students with lower qualified parents and low academic effective primary school and students with higher qualified parents were the largest for those who had attended a highly effective primary school ($ES_{\text{Orig}}=0.57$; $ES_{\text{Imputed}}=0.49$).

Figure 3.23: The Combined Impact of Parents' Highest Qualification and Primary School Academic Effectiveness (Maths) on Science Teacher Assessment Levels in Year 9

The Combined Impact of Pre-School Experience and Primary School Academic Effectiveness

Given that the study has demonstrated both the importance of characteristics of pre-school experience and the impact of primary school academic effectiveness for long lasting positive effects on later academic attainment, their joint effects were also investigated in Year 9. We sought to establish whether going to a high quality or more effective pre-school had a protective influence if a child went on to a less effective primary school, and whether 'home' students, or those who went to a less effective or low quality pre-school, did better later if they went to a more effective primary school and whether these effects continued into secondary school.

We combined different pre-school measures and primary school academic effectiveness and incorporated them in the same model - controlling for background factors - to explore any joint effects of pre-school and primary school. For all three subjects, the reference group was 'no pre-school and low academically effective primary school'.

High academically effective primary school boosted later academic attainment regardless whether the child had attended or not a pre-school. However, these boosting effects were statistically significant only for maths and science, and did not reach significance level for English (see Table 3.32 - Table 3.33).

* $p < 0.05$

We also combined the measure of pre-school quality (ECERS-E) with primary school academic effectiveness. We included these joint measures in the same multilevel model that also contained the individual student, family and HLE measures. Only the results for maths and science are presented as for English, the combined term of pre-school quality and primary school academic effectiveness was not statistically significant (see Table 3.34-Table 3.35; Figure 3.24-Figure 3.25).

For maths, the quality of the pre-school attended still shows a protective function for those students who attended a low academically effective primary school. Thus, students who had attended a high quality pre-school but later went to a low academically effective primary school had greater TA levels ($ES_{\text{Orig}}=0.48$; $ES_{\text{Imputed}}=0.54$) in maths than those who had not attended any pre-school but later had attended a low academically effective primary school. Similarly for medium quality pre-schools; the difference in attainment between students who had not attended a pre-school and a low academically effective primary school and students who had not attended a pre-school but then went to a medium academically effective primary school was statistically significant and positive in favour for the later group ($ES_{\text{Orig}}=0.43$; $ES_{\text{Imputed}}=0.48$). Students who had attended a moderate to high academically effective primary school performed significantly better, regardless of the pre-school's quality, than those who had not attended any pre-school and in a primary school of low academic effectiveness (see Figure 3.24).

Figure 3.24: The Combined Impact of Pre-school Quality (ECERS-E) and Primary School Academic Effectiveness on Maths Teacher Assessment Levels in Year 9

For Science, the protective influences of pre-school were more noticeable; regardless of the attended pre-school’s quality, students who continued their education in low academically effective²⁴ primary school performed as well as those who continued in moderate or high academically effective primary school, indicating that attending a pre-school still predicted better academic attainment in different subjects and for a long period of time (see Figure 3.25).

Also, primary school had a statistically significant positive influence on the academic attainment of those students who had not attended any pre-school. For both maths and science, students who went to a high academically effective primary school but had not attended a pre-school obtained significantly higher TA levels than those who went to a low academically effective primary school and did not go to a pre-school (maths: $ES_{Orig}=0.40$; $ES_{Imputed}=0.47$; science: $ES_{Orig}=0.71$; $ES_{Imputed}=0.61$).

²⁴ It should be noted that the measure of primary school academic effectiveness tested related to Maths and not Science.

Figure 3.25: The Combined Impact of Pre-school Quality (ECERS-E) and Primary School Academic Effectiveness (Maths) on Science Teacher Assessment Levels in Year 9

The Combined Impact of Pre-School Effectiveness and Primary School Academic Effectiveness

In addition to the analyses of the individual impact of pre- and primary school academic effectiveness, these two measures were taken together so that the combined effects could be explored. The questions were whether going to a more effective pre-school had a protective influence if a child went on to a less effective primary school, and whether 'home' students or those who went to a less effective pre-school centre did better later if they went to a more effective primary school. Only the results for maths and science are presented as for English the combined term of pre-school effectiveness and primary school academic effectiveness was not statistically significant (see Table 3.36 and Table 3.37; Figure 3.26 and Figure 3.27). The reference group for these analyses were students with no pre-school experience who attended a low academically effective primary school.

Figure 3.26 and Figure 3.27 show for both maths and science that the students who were educated in low academically effective primary schools but had previously attended pre-school were still benefiting from that pre-school experience in Year 9. Their academic attainment in maths and science were gradated by the level of pre-school effectiveness. Thus, the highest attainment of the students educated in low academically effective primary schools was obtained by those who had attended a highly effective pre-school when compared to those from similar primary schools with no pre-school experiences (maths: $ES_{\text{Orig}}=0.63$; $ES_{\text{Imputed}}=0.70$; science: $ES_{\text{Orig}}=0.99$; $ES_{\text{Imputed}}=0.92$). These highly attaining group of students from low effective primary schools were then followed in decreasing order by those who had attended medium effective pre-schools and then by those who attended low effective pre-school.

Students who continued their education in high academic effective primary schools had similar levels of attainment regardless of the level of pre-school effectiveness when compared to those from low academic effective primary schools with no pre-school. The clear benefit of attending high academically effective primary school was shown for students who did not have any pre-school experiences. For attainment in both maths and science, students who went to a high academically effective primary school but had not attended a pre-school obtained significantly higher TA levels in Year 9 than those who had attended to a low academically effective primary school and did not go to a pre-school (maths: $ES_{\text{Orig}}=0.40$; $ES_{\text{Imputed}}=0.47$; science: $ES_{\text{Orig}}=0.71$; $ES_{\text{Imputed}}=0.61$).

Figure 3.27: The Combined Impact of Pre-school Effectiveness (Early Number Concepts) and Primary School Academic Effectiveness (Maths) on Science Teacher Assessment Levels in Year 9

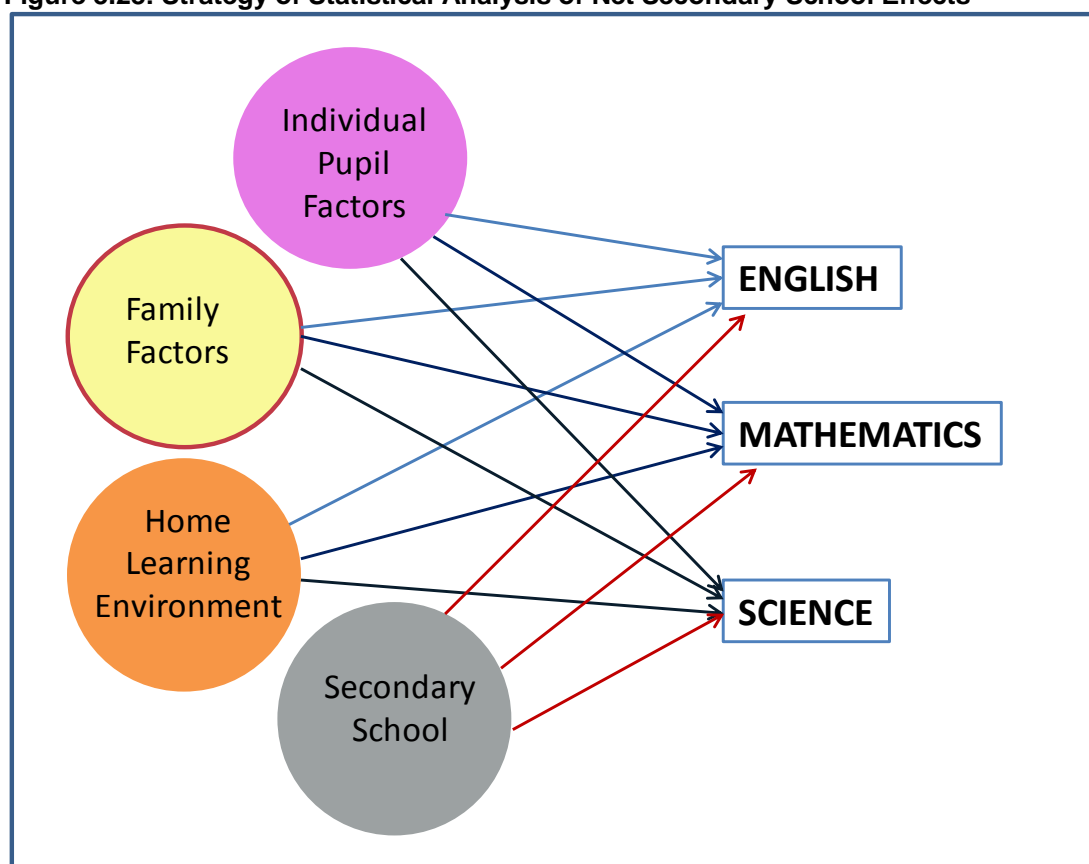

Overall, the findings extend earlier work conducted for the EPPSE sample up to age 11. These is evidence that the effectiveness of the pre-school continues to shape academic outcomes into lower secondary school and also that the academic quality of the primary school also shapes outcomes. Thus, the earlier educational experiences can offer longer term benefits to academic attainment.

3.3. The Impact of Secondary School on Year 9 Attainment

Analyses in the last section have shown that the academic effectiveness of the primary school predicts students' attainment in KS3 (particularly in maths and science) over and above that attributed to students' background. It is therefore important to establish whether secondary school effectiveness and educational quality also help to predict better student outcomes at age 14. In order to do this, national data sets have been used to obtain indicators of the level of secondary schools academic effectiveness and quality.

The measures of secondary school academic effectiveness and quality were added to the contextualised models that predicted attainment in Year 9 English, maths and science when controlling for individual student, family and HLE characteristics (see Figure 3.28 for the statistical analysis strategy).

Figure 3.28: Strategy of Statistical Analysis of Net Secondary School Effects

3.3.1. The Impact of Secondary School Academic Effectiveness on Year 9 Attainment

The secondary school academic overall effectiveness was represented by the contextual value added (CVA) score at the school level. This measure²⁵ was provided by the DfE²⁶ and was matched into our data set based on the school identification number.

A mean CVA score was calculated based on KS2 to KS4 (KS2-4) CVA scores for four years from 2006 to 2009 for the secondary schools attended by EPPSE students. This measure was then incorporated into the multilevel models that predicted attainment in Year 9 English, Maths and Science when controlling for individual student, family and HLE characteristics.

We did not find a statistically significant overall effect of the secondary school academic effectiveness for any of the academic outcomes. It has to be noted that the secondary school academic effectiveness is a measure that was used as an overall progress across 5 years and did not relate to the KS3 period. Also, this measure might not relate in the same way with specific academic outcomes as a subject specific academic effectiveness (our earlier analyses on subject specific academic effectiveness measures at primary school indicated that this is relevant).

3.3.2. The Impact of Secondary School Quality on Year 9 Attainment

The quality of secondary schools was measured by Ofsted school level inspection judgements. These judgements cover four dimensions at the school level:

- a) overall effectiveness,
- b) achievement and standards,
- c) personal development and well-being
- d) quality of provision.

Secondary schools were given grades from 1 to 4, where Grade 1 meant that the secondary school was outstanding, Grade 2 – secondary school was good, Grade 3 – secondary school was satisfactory and Grade 4 – meaning that the secondary school was inadequate.

Since secondary schools are inspected in different years, we collected Ofsted inspection judgements from 2005 until 2010²⁷. When a secondary school had several Ofsted inspection judgements, we considered the earliest one in time. The judgements pertaining to the four dimensions mentioned were tested in the contextualised models that predicted academic attainment in Year 9, controlling for individual, family and HLE characteristics (see Appendix 9 for an exhaustive list of the tested Ofsted inspection judgements). Each inspection judgement was entered separately in the model so we avoid potential collinearity problems.

²⁵ At the student level, the CVA score was calculated as the difference between predicted attainment (i.e., the average attainment achieved by similar students) and real attainment in KS4. The predicted attainment was obtained by using multi-level modelling when controlling for students' prior attainment and adjusting for their background characteristics (i.e., gender, age, ethnicity, special educational needs, FSM, mobility etc.). For each school, all individual student scores were averaged and adjusted for the proportion of students attending the school in a specific year. This final averaged score represents the school level CVA and it is presented as a number based around 1000 (for more technical details see http://www.education.gov.uk/performance/tables/schools_08/2007_2008_Guide_to_CVA.pdf).

²⁶ However, DfE no longer uses this approach. A value added measure is used instead which compares progress, but does not take background into account. The pupil's value added score is based on comparing their exam performance with the median exam performance of other pupils with the same or similar prior attainment at Key Stage 2. The median value is the middle value - with half of the pupils having a capped point score at or below the median, and half at or above. A school's value added measure is a simple average (arithmetic mean) of the value added scores for all pupils in the school. http://www.education.gov.uk/performance/tables/schools_05/sec9.shtml

²⁷ These were downloaded from the Ofsted homepage <http://www.ofsted.gov.uk/>

Only two Ofsted inspection judgements proved to be significant predictors of students' academic attainment in Year 9: the 'quality of pupils' learning and their progress' (pertaining to the 'achievement and standards' dimension) and the 'attendance of learners' (part of the 'personal development and well-being' dimension).

The Impact of the Quality of Pupils' Learning and Their Progress on Year 9 Attainment

Students attending secondary schools classified as outstanding based on the quality of pupils' learning had significantly better average results in English ($ES_{\text{Orig}}=0.42$; $ES_{\text{Imputed}}=0.41$), maths ($ES_{\text{Orig}}=0.56$; $ES_{\text{Imputed}}=0.57$) and science TA levels ($ES_{\text{Orig}}=0.51$; $ES_{\text{Imputed}}=0.54$) than students from secondary schools characterised as inadequate in their learning quality.

Additionally, students from secondary schools characterised as good or even satisfactory on learning quality performed significantly better in maths than students from inadequate secondary schools (see Table 3.39).

It is not surprising to find a strong relationship between the overall quality of learning in a specific secondary school and learning outcomes of its students; an outstanding provision leading to higher levels of attainment.

The Impact of the Learners' Attendance on Year 9 Attainment

Ofsted inspectors rated secondary schools based on the level of attendance of their students. Learners' attendance as rated by Ofsted inspectors was a statistically significant predictor of academic attainment in Year 9 in all three subjects. Students from secondary schools rated as outstanding on the learners' attendance got higher average levels in English ($ES_{\text{Orig}}=0.70$; $ES_{\text{Imputed}}=0.64$), maths ($ES_{\text{Orig}}=0.71$; $ES_{\text{Imputed}}=0.69$) and science TA ($ES_{\text{Orig}}=0.56$; $ES_{\text{Imputed}}=0.54$) than students from secondary schools characterised as inadequate in their overall attendance (see Table 3.41 - Table 3.43).

Additionally, students from secondary schools characterised as good or even satisfactory on attendance performed significantly better in English, maths and science than students from inadequate secondary schools.

The relationship between overall attendance and academic outcomes is interesting, but not straightforward. The positive strong relationship might be due to the fact that secondary schools that offer high quality academic provision have stricter policies on attendance and therefore are better attended, or are better attended because of the very quality of the provision. Additionally, we could not dismiss the benefits of higher levels of attendance on academic attainment. At this point, we could only speculate about these complex relationships.

3.3.3. The Combined Impact of Pre-School Experience and Secondary School Academic Effectiveness

Even though we did not find a statistically significant overall effect of the secondary school academic effectiveness, it was important to explore whether features of the secondary school in combination with certain characteristics of the pre-school or primary school would have any influences on academic attainment in Year 9. We wanted to establish whether going to a high quality or more effective pre-school had a protective influence for students who later went to a less effective secondary school, and whether 'home' students, or those who went to a less effective or low quality pre-school, did better later if they went to a more effective secondary school.

Therefore, we combined different pre-school measures (i.e., quality and effectiveness) and secondary school academic effectiveness and incorporated them in the same model - controlling for background factors - to explore any joint effects of pre-school and secondary school. For all three subjects, the reference group was 'no pre-school and low academically effective secondary school'. The results of the combined effects between pre-school quality and secondary school academic effectiveness are presented in Table A.7.1 - Table A.7.3 in Appendix 7.

The benefits of pre-school quality for later attainment in English, maths and science are only visible only for those who were attending a medium effective secondary school in Year 9. The results for the other two groups (low and high effective secondary schools) are harder to interpret. The levels of attainment for this 'middle' group are gradated based on the quality of the attended pre-school. Thus, for all three subjects, students who had attended a low, medium or high quality pre-school

showed better attainment than those who had never attended a pre-school (given that they were all in a medium effective secondary school (see Figure A.7.1- Figure A.7.3 in Appendix 7).

The combined term between pre-school effectiveness and secondary school academic effectiveness show a similar pattern as the combined term between pre-school quality and secondary school effectiveness. However, the gradation in attainment based on pre-school effectiveness was visible not only for the medium effective secondary schools but also for the low effective secondary schools (see Figure A.7.4 and Figure A.7.6 in Appendix 7).

For all three subjects, the progression in attainment from no pre-school to highly effective pre-schools lead to increase in outcome in low effective secondary schools, students having attended a highly effective pre-school receiving the highest attainment levels when compared to students who had not attended any pre-school.

Similarly, this was the case for medium effective secondary schools. The differences in attainment from no pre-school and low secondary school effectiveness increased as the level of pre-school effectiveness improved, with the largest difference being for students who had attended highly effective pre-schools.

3.4. Summary of Pre-, Primary and Secondary School Influences

The contextualised multilevel models tested the net impact of different aspects of pre-, primary and secondary school experience while controlling for all other background measures simultaneously. These models provide rigorous and conservative estimates of statistical significance of any continuing pre- and primary school effects on later attainment in Year 9 as well as of secondary school influence.

The contextualised analyses show that good pre-school experience (in terms of high quality and high effectiveness) can still make a difference to students' longer term academic attainment even after 9 years full time in primary and secondary school education (for maths and science).

The results also illustrated that the academic effectiveness of the primary school also matters for attainment in maths and science in Year 9. A high academic effective primary school seems to be important for those students who did not go to pre-school (the lowest attainment are for the no pre-school group who went on to a low academically effective primary school). On the other hand attending high quality or more effective pre-school seems to act as a moderate to strong protective factor for students who go on to attend a less academically effective primary school.

No main effect was found for the secondary school academic effectiveness for any of the three academic subjects. However, the quality of the secondary school measured by the Ofsted inspection judgement proved to be significant predictor of academic attainment in Year 9. Students who attended outstanding secondary school as rated by the Ofsted inspectors in terms of attendance and quality of learning obtained significantly higher levels of TA in English, maths and science.

4. Exploring the Effects of School, Teaching Processes and Students' Views of Themselves on Later KS3 Attainment

During Year 9, students completed two questionnaires about their personal and academic life while in secondary school. One questionnaire ('All about me in school') focused on their academic life, specifically on their perceptions of the school, their teachers, headteachers and other students but also on their experiences as students in secondary schools. Based on this survey, several indicators were created reflecting school and teaching processes (for details see Sammons et al., 2011b).

The second questionnaire ('All about me') explored in more detail the personal, familial and the broader social context of the students while in secondary school. Interesting domains like 'out of school' learning along with the opportunities students have for additional learning experiences 'after hours', time spent on homework and the way they developed their own self academic concepts regarding different subjects were investigated.

It was hypothesised that all these various experiences might have an impact on the students' academic attainment. Therefore, we tested the indicators of school and teaching processes as predictors of the Year 9 academic outcomes measured by the TA levels in the multilevel models that controlled for individual student, family and HLE characteristics. These analyses provide an insight about the way secondary school experiences help to predict variation in students' academic outcomes in Year 9.

4.1. Teaching and School Processes

First, we explored the students' school related perceptions and experiences. Using Exploratory and Confirmatory Factor Analysis (EFA & CFA) several factors related to teaching and school processes were created (see Sammons et al., 2011b). These factors included:

- Emphasis on learning
- Behaviour climate
- Headteacher
- School environment
- Valuing pupils
- School/Learning resources
- Teacher behavioural management
- Teacher support

These factors were tested as separate predictors of the Year 9 academic outcomes in multilevel models that also included various individual student, familial and HLE characteristics (described as important in Sections 2 and 3). For each academic outcome a number of school factors were found to be statistically significant. Originally, the items that entered in the composition of any of the factors were Likert type scale that went from (1) strongly agree to (4) strongly disagree. These were reversed in order to make the interpretation easier. The factors were treated as continuous measures and were centred to the grand mean. Only the factors that were significant predictors of Year 9 academic attainment are presented.

4.1.1. Emphasis on Learning

Emphasis on learning describes the perceived expectations that teachers have regarding their students' learning, but also the students' expectations regarding their own attainment. A higher emphasis on learning was a significant predictor of better attainment measured by TA levels in English ($ES_{\text{Orig}}=0.21$; $ES_{\text{Imputed}}=0.21$), maths ($ES_{\text{Orig}}=0.22$; $ES_{\text{Imputed}}=0.21$) and science ($ES_{\text{Orig}}=0.20$; $ES_{\text{Imputed}}=0.16$). In terms of gain in academic attainment, higher emphasis on learning was associated with an increase of half of a TA level in English and science and more than three quarters of a TA level in maths.

% Reduction total variance	37%				32%			

* $p < 0.05$

²⁸ These analyses are based on a further imputation model that incorporated additional measures of students' self-perceptions.

4.1.2. Behaviour Climate

Behaviour climate refers to the specific (disruptive) behaviours that students notice around the school (e.g., obeying rules, fighting, bringing into schools knives or weapons). Higher scores on this factor reflect a more positive behaviour climate²⁹. The results of the multilevel models predicting academic attainment indicated that the TA levels in English, maths and science were higher for students who perceived their secondary schools' behaviour climate as more positive than those who rated the behaviour climate of their schools less favourably (see Table 4.4 and Table 4.6). The ES for maths and science were larger than for English.

These results are in accord with previous school effectiveness research that points to the importance of the school's overall behaviour climate (see Creemers & Kyriakides, 2008; Rutter et al., 1979; Sammons, Thomas, & Mortimore, 1997; Scheerens & Bosker, 1997).

²⁹ Students rate their school more positively in terms of the extent of disruptive behaviours

4.1.3. School Environment

The school environment measure represents the perceived quality of the physical environment of the secondary school (i.e., attractive building, decoration of the classroom, level of cleanness of the toilets) but also the level of organisation. The environment in which teaching and learning take place is found to predict the students' academic attainment. Thus, students who perceived their school's environment as pleasant and attractive achieved better TA levels than those who did not. The school environment was found to be a statistically significant predictor of TA levels in both maths and science but it was not significantly related to the English TA levels (see Table 4.7-Table 4.8).

* $p < 0.05$

4.1.4. Valuing Pupils

Another domain that predicted the academic outcome was students' perceptions of the degree in which their teachers valued and respected them. Higher scores on this factor reflect higher perceived levels of respect and friendliness from the teachers. The more the teachers were perceived as valuing pupils' views and opinions, the higher the academic outcome in maths ($ES_{\text{Orig}}=0.12$; $ES_{\text{Imputed}}=0.09^{\text{ns}}$) and science ($ES_{\text{Orig}}=0.14$; $ES_{\text{Imputed}}=0.09^{\text{ns}}$), although positive, the ES were small. As with all self-perception measures, it is not possible to make causal connections since the directionality of relationships may be reciprocal. Students with higher attainment may have more positive perceptions of their teachers. Additionally, teachers who value their students could also put more effort in the teaching and learning and therefore increase academic attainment. Regardless of the specific directionality, it is important for the teachers to recognise that the way they relate and present themselves to the students may influence their academic outcome.

Table 4.9: Contextualised Models for Maths Teacher Assessment Levels in Year 9: Valuing pupils (Original Data vs. Imputed Data)

% Reduction student variance	21%				14%			
% Reduction total variance	37%				31%			

* $p < 0.05$

4.1.5. School/Learning Resources

The schools' capacity to offer good learning resources is likely to influence the way students learn and acquire new information. Amenities like good science labs, libraries and computer rooms were directly associated with academic outcome, especially in maths and science. Again, higher scores on learning resources meant that the students perceived that the school was well equipped with computers and technology and that there was enough time in using these facilities. Students' perceptions of available learning resources significantly predicted higher TA levels in maths and science (see Table 4.11 and Table 4.12), although the ES were small and significantly only in the original data. Thus, students' academic attainment in maths and science increased with half of a level when more learning resources were available.

Table 4.11: Contextualised Models for Maths Teacher Assessment Levels in Year 9: Learning Resources (Original Data vs. Imputed Data)

* $p < 0.05$

4.1.6. Emphasis on Learning and Behaviour Climate

After testing each of the eight factors derived from the Year 9 student survey separately as predictors of attainment, we also tested them together to investigate which ones are the most important in predicting academic outcomes in Year 9 when still controlling for individual student, familial and HLE characteristics. Because the factors were correlated the question of multicollinearity arises. For all three core curriculum subjects, it was found that the two factors 'emphasis on learning' and 'behaviour climate' together significantly predicted Year 9 academic attainment. Additionally, it when tested together the factor 'behaviour climate' is found to be the stronger predictor of academic attainment. Also, for maths, the ES is slightly larger than the ES found in the equivalent analyses for English and science TA levels ($ES_{\text{Orig}}=0.43$; $ES_{\text{Imputed}}=0.47$) as can be seen in Table 4.14. For attainment in all areas a stronger 'emphasis on learning' and a more positive rating of their school's 'behaviour climate' – as they were perceived by students – significantly predicted better attainment in all three subjects.

Table 4.13: Contextualised Models for English Teacher Assessment Levels in Year 9: Emphasis on Learning and Behaviour Climate (Original Data vs. Imputed Data)

% Reduction school variance	88%				89%			
% Reduction student variance	23%				17%			
% Reduction total variance	38%				34%			

* $p < 0.05$

These results again point to the importance of the secondary school's behaviour climate as an important feature of effectiveness, and this supports the findings of previous research on secondary schools (e.g., Rutter et al., 1979; Sammons, Thomas & Mortimore, 1997).

4.2. Time Spent on Homework

Students' self reports of time spent on homework was positively linked to higher TA levels for all three subjects, the biggest effect sizes were obtained for the category '2-3 hours'. The relationship between time spent on homework and TA levels followed an incremental gradation up to 2-3 hours. Spending more than 3 hours on homework did not offer extra benefits for attainment in this analysis. The highest benefit of studying for 2-3 hours was found for science ($ES_{\text{Orig}}=0.85$; $ES_{\text{Imputed}}=0.65$), followed by maths ($ES_{\text{Orig}}=0.84$; $ES_{\text{Imputed}}=0.71$) and finally for English ($ES_{\text{Orig}}=0.73$; $ES_{\text{Imputed}}=0.65$). Studying for more than 3 hours significantly predicted higher TA levels in English and maths, but only for the original data.

Time spent on homework was one of the strongest predictors of attainment even when students' background was controlled. Time spent on homework may reflect teachers' expectations and the schools' academic emphasis as well as the students' own motivation and engagement. Our findings are in line with previous research on the homework and academic achievement relationship (Cooper et al., 2006; Holmes & Croll, 1989).

4.3. Students' Views of Themselves

Based on the 'All about me' questionnaire, the following indicators were created (see Sammons et al., 2011b report for the technical details of obtaining these factors):

- Maths Academic Self-Concept
- English Academic Self-Concept
- Enjoyment of School
- Popularity
- Citizen Values
- Anxiety Behaviours

These factors were entered separately as predictors of the Year 9 academic outcomes in multilevel models that also included individual student, familial and HLE characteristics. For each academic outcome, different school factors were significant. Lower scores on these factors indicate higher degrees of agreement with the items that entered in the composition of the specific factor. Similarly with the indicators of the teaching and school processes, these factors were also treated as continuous measures and were centred to the grand mean. Only the factors that were significant predictors of Year 9 academic attainment are presented.

4.3.1. Maths and English Academic Self-Concepts

Students own perceptions of their abilities in maths and English were highly predictive of academic attainment in Year 9. As expected, the academic self-concept in maths was the strongest predictor of the maths TA levels ($ES_{\text{Orig}}=1.15$; $ES_{\text{Imputed}}=1.02$). This was also a strong predictor of science ($ES_{\text{Orig}}=0.76$; $ES_{\text{Imputed}}=0.68$) and English TA levels ($ES_{\text{Orig}}=0.47$; $ES_{\text{Imputed}}=0.51$). Similarly, the English academic self-concept was the strongest predictor of the English TA levels ($ES_{\text{Orig}}=0.74$; $ES_{\text{Imputed}}=0.66$).

In interpreting these findings, it should be noted that academic self-concept is likely to be strongly influenced by earlier and current attainment and the links are reciprocal (Marsh & O'Mara, 2008).

The maths academic self concept was a better predictor of English TA levels ($ES_{\text{Orig}}=0.47$; $ES_{\text{Imputed}}=0.51$) than the English academic self-concept predicting maths TA levels ($ES_{\text{Orig}}=0.23$; $ES_{\text{Imputed}}=0.31$). Moreover, the academic self-concept in maths was a stronger predictor of the science TA levels ($ES_{\text{Orig}}=0.76$; $ES_{\text{Imputed}}=0.68$) than the academic self-concept in English predicting the same academic outcome - science ($ES_{\text{Orig}}=0.38$; $ES_{\text{Imputed}}=0.39$).

These findings are in line with previous research that showed that self-concept effects on academic achievement tended to be greater and more systematic for maths than for science and, particularly, English (Marsh & Yeung, 1997).

4.3.2. Enjoyment of School

The degree to which students enjoyed their school was a statistically significant predictor of their attainment in Year 9. Students who liked being at school or found the school as a friendly place were also more likely to obtain higher TA levels in English ($ES_{\text{Orig}}=0.29$; $ES_{\text{Imputed}}=0.22$), maths ($ES_{\text{Orig}}=0.38$; $ES_{\text{Imputed}}=0.28$) and science ($ES_{\text{Orig}}=0.31$; $ES_{\text{Imputed}}=0.23$).

Again in interpreting these results, it should be noted that these relationships are reciprocal. Enjoyment may be influenced by academic success and vice versa.

% Reduction total variance	38%				32%			

* $p < 0.05$

4.3.3. Anxiety Behaviours

Anxious behaviour was a negative predictor of academic outcome. As might be anticipated, students who rated themselves more highly in terms of anxiety had poorer attainment levels (see Table 4.28 and Table 4.30). Anxiety had its strongest negative effect on attainment in maths ($ES_{\text{Orig}}=-0.29$; $ES_{\text{Imputed}}=-0.16$), more anxious students losing almost half of TA level when compared to less anxious students.

5. Exploring Relative Academic Progress between Year 6 and Year 9

Young students' academic progress was investigated over the pre-school period, from age 3 years plus to primary school entry (Sammons et al., 2002). The results were used to identify measures of pre-school centre effects, based on value added analyses, tested in earlier sections of this report in relation to attainment at the end of Year 9.

Further analyses of progress were reported between Year 1 and Year 5 (Sammons et al., 2007a) and then between Year 2 and Year 6 of primary education (Sammons et al., 2008a). In this section, we explore the EPPSE students' academic progress from the end of Year 6 at primary school to the end of Year 9 at secondary school using TA levels as academic outcomes and Year 6 National Assessment test scores as measures of prior attainment. The assessments at the end of Year 6 provide the baseline measures for these analyses of student progress. The results of the simple value added models control only for prior academic attainment at the end of Year 6 for prediction of later attainment in English, maths and science at the end of Year 9.

The results indicate that more of the total variance in maths TA levels in Year 9 was accounted for by prior attainment at the end of Year 6 (71%) than is the case for English (58%) or science TA levels (54%). The results indicated that around 10 to 11 per cent of the variation in progress is accounted for by the secondary school attended (see Table 5.2 - Table 5.4).

The variation in students' progress associated with their school is shown by the intra-school correlation (ICC) an overall indicator of potential differences in school effectiveness. It is possible that any variation between schools, in terms of progress, might reflect differences in teaching approaches and emphases during KS3.

Table 5.1 shows the estimates for the academic attainment at the end of Year 6 measured by National Assessments when predicting English, maths and science TA at the end of Year 9. Prior attainment in English was considered to be relevant for later attainment in English, with an estimate of 0.04, while the prior attainment in maths was relevant for later attainment in maths, with an estimate of 0.07. When tested individually, the prior attainment in maths proved to be a stronger predictor for later attainment in science (estimate=0.05) than the prior attainment in English (estimate=0.04). This is also the case when both prior attainment are tested together in predicting later science TA levels.

Table 5.1: Multilevel Model Estimates of Prior Attainment Measures on Year 9 attainment in English, Maths and Science Outcomes – Original Data

	English TA (Year 9)	Maths TA (Year 9)	Science TA (Year 9)
	Estimate (se)	Estimate (se)	Estimate (se)

5.1. The Impact of Individual Student, Family and Home Learning Environment (HLE) characteristics

After the simple value added analyses, further contextualised value added analyses were undertaken to explore whether the individual student, family and HLE characteristics, found to be significant predictors of later academic attainment differences at the end of Year 9, were also associated with differential academic progress between primary and secondary school (see Figure 5.1 for an illustration).

Figure 5.1: Strategy of Statistical Analysis of the Impact of Prior Attainment

The findings indicated that older students compared to younger students ($ES_{\text{Orig}}=0.24$; $ES_{\text{Imputed}}=0.20$), girls compared to boys ($ES_{\text{Orig}}=0.32$; $ES_{\text{Imputed}}=0.25$), students with older mothers ($ES_{\text{Orig}}=0.13$; $ES_{\text{Imputed}}=0.09$), students' whose family's income was very high ($ES_{\text{Orig}}=0.39$; $ES_{\text{Imputed}}=0.21^{\text{ns}}$), students who have highly qualified mothers ($ES_{\text{Orig}}=0.34$ or $ES_{\text{Imputed}}=0.22$ for mothers with degree/high degree compared to no qualification) or fathers ($ES_{\text{Orig}}=0.28$ or $ES_{\text{Imputed}}=0.19^{\text{ns}}$ for fathers with degree/high degree compared to no qualification) and that students who had a medium KS2 HLE ($ES_{\text{Orig}}=0.16$; $ES_{\text{Imputed}}=0.10^{\text{ns}}$) made significantly better progress in English. On the other hand, students whose parents reported one or more early behavioural problems in the pre-school period ($ES_{\text{Orig}}=-0.15$; $ES_{\text{Imputed}}=-0.14$ compared to no behavioural problems), students eligible or receiving FSM ($ES_{\text{Orig}}=-0.19$; $ES_{\text{Imputed}}=-0.17$ as compared to no FSM), students from schools that have a higher proportion of FSM students ($ES_{\text{Orig}}=-0.18$; $ES_{\text{Imputed}}=-0.14$) made significantly less progress during secondary school education. For the detailed ES see Table 5.5.

For maths, the results showed that older students compared to younger students ($ES_{\text{Orig}}=0.32$; $ES_{\text{Imputed}}=0.24$), girls compared to boys ($ES_{\text{Orig}}=0.16$; $ES_{\text{Imputed}}=0.12$), students of other ethnic minority ($ES_{\text{Orig}}=0.31$; $ES_{\text{Imputed}}=0.25^{\text{ns}}$) or of Bangladeshi background ($ES_{\text{Orig}}=0.88$; $ES_{\text{Imputed}}=0.62$) and that students who have highly qualified fathers ($ES_{\text{Orig}}=0.28$ or $ES_{\text{Imputed}}=0.13^{\text{ns}}$ for fathers with degree/high degree compared to no qualification) made greater gains in terms of progress during secondary school. However, students whose parents reported one or more early behavioural problems in the pre-school period ($ES_{\text{Orig}}=-0.14$; $ES_{\text{Imputed}}=-0.17$ compared to no behavioural problems) and students eligible or receiving FSM ($ES_{\text{Orig}}=-0.19$; $ES_{\text{Imputed}}=-0.17$ as compared to no FSM) made significantly less progress in maths (see Table 5.6).

* $p < 0.05$

As the relationship between Year 9 science TA levels and Year 6 Maths test scores was stronger than with Year 6 English test scores, the prior attainment in Maths was included in the value added models.

For the attainment in science, it was found that older students compared to younger students ($ES_{\text{Orig}}=0.20$; $ES_{\text{Imputed}}=0.15$), girls compared to boys ($ES_{\text{Orig}}=0.17$; $ES_{\text{Imputed}}=0.14$), White European students ($ES_{\text{Orig}}=0.38$; $ES_{\text{Imputed}}=0.26$) or of Bangladeshi origin ($ES_{\text{Orig}}=0.54$; $ES_{\text{Imputed}}=0.47^{\text{ns}}$), students with older mothers ($ES_{\text{Orig}}=0.15$; $ES_{\text{Imputed}}=0.09$), students who have highly qualified mothers ($ES_{\text{Orig}}=0.33$ or $ES_{\text{Imputed}}=0.26$ for mothers with degree/high degree compared to no qualification) or fathers ($ES_{\text{Orig}}=0.43$ or $ES_{\text{Imputed}}=0.21$ for fathers with degree/high degree compared to no qualification) and that students who had a medium KS2 HLE ($ES_{\text{Orig}}=0.10$; $ES_{\text{Imputed}}=0.11^{\text{ns}}$) made significantly better progress in science in secondary school (see Table 5.7).

A few categories of students made significantly less progress during secondary school: students eligible or receiving FSM ($ES_{\text{Orig}}=-0.15$; $ES_{\text{Imputed}}=-0.16$ as compared to no FSM) and students from schools that have a higher proportion of FSM students ($ES_{\text{Orig}}=-0.21$; $ES_{\text{Imputed}}=-0.15$).

These results confirm the findings identified at younger ages for the EPPSE sample in both pre-school and primary school and show the continued impact of such background factors in shaping both students' attainment and progress in different phases of education.

Additionally, some of the neighbourhood variables that were discussed previously in Section 2.4 “Neighbourhood Influence” were tested in the progress models for English, maths and science. For progress in maths, none of the neighbourhood measures were statistically significant. However, the level of crime in the neighbourhood and the percentage of White British citizen in the neighbourhood were significant predictors of progress in English, indicating that students from neighbourhoods characterised by a higher level of crime or with higher percentage of White British residents made less progress in English during KS3.

Progress in science was also sensitive to neighbourhood influences. The Index of Multiple Deprivation (IMD) scores and IDACI, level of crime and perceived neighbourhood safety were all found to be significant predictors of students’ progress in science during secondary school. The results showed that the higher the IMD or IDACI scores indicating greater levels of neighbourhood disadvantage, the poorer the academic progress in science. Moreover, students from neighbourhoods characterised by a higher level of crime or as being less safe also made less progress in science.

In primary school in Year 6, the neighbourhood measures were not found to be significant for academic progress during KS2. These measures became important, however, for the academic progress in secondary school. This may be because as students grow older they are probably more involved in activities outside the home and with their peer group.

5.2. The Impact of Pre-, Primary and Secondary School Experience

Since multiple dimensions of the pre-, primary and secondary experiences proved to be significant predictors of students' academic attainment in Year 9, we sought to establish whether any of the same characteristics would also be significant predictors of students' academic progress between Year 6 and Year 9. Results showed that the pre-school and primary school experiences were no longer associated with the amount of academic progress students made during secondary school, although they still have been shown to still shape attainment in Year 9. On the other hand, the academic effectiveness of the secondary school was significant only for English and the two Ofsted measures of secondary school quality were significant predictors of students' progress in English, maths and science in KS3.

5.2.1. The Impact of Secondary School Academic Effectiveness

The secondary school academic effectiveness measured by the school level CVA was a significant predictor of progress in English (see Table 5.8). Students from highly (for the original data) or medium (for the imputed data) effective secondary schools made significantly more progress in English than students from low effective secondary schools³⁰.

Table 5.8: Contextualised Value Added Models for English Teacher Assessment Levels in Year 9: Secondary School Academic Effectiveness (Original Data vs. Imputed Data)

	Year 9 English TA Original Data				Year 9 English TA Imputed Data STATA ICE

% Reduction student variance	56%				48%			
% Reduction total variance	64%				57%			

* $p < 0.05$

5.2.2. The Impact of Secondary School Quality

In addition to the CVA indicators, Ofsted inspection data provided further measures of school quality. Secondary schools' quality measured by Ofsted inspection judgements was found to be predictor of academic progress in secondary school. The same measurements of secondary school quality which were statistically significant predictors of academic attainment proved to be important for academic progress as well in KS3. The 'quality of pupils' learning and their progress and the 'attendance of learners' were positive predictors of academic progress in English, maths and science.

³⁰ Because CVA scores were not available for all secondary schools, the measure was divided into groups – high, medium, low and missing to avoid reducing the sample size. It was deemed inappropriate to impute missing school CVA measures in this data set.

The Impact of the Quality of Pupils' Learning on Academic Progress in Secondary School

EPPSE students attending secondary schools classified as outstanding in terms of inspection judgements of the 'quality of pupils' learning' made significantly greater progress in English ($ES_{\text{Orig}}=0.36$; $ES_{\text{Imputed}}=0.34$), maths ($ES_{\text{Orig}}=0.32$; $ES_{\text{Imputed}}=0.40$) and science TA levels ($ES_{\text{Orig}}=0.29$; $ES_{\text{Imputed}}=0.35$) than students from secondary schools characterised as inadequate in their learning quality.

Moreover, their progress in maths was significantly greater for those attending secondary schools characterised as good or satisfactory on learning quality than the progress of the students from inadequate secondary schools (see Table 5.10). The size of effects was moderately strong and showed a clear trend.

The Impact of the Learners' Attendance on Academic Progress in Secondary School

Academic progress in secondary school was also significantly related to the Ofsted judgement of learners' attendance. Students attending secondary schools rated as outstanding on the learners' attendance had greater gains in English ($ES_{\text{Orig}}=0.48$; $ES_{\text{Imputed}}=0.46$) and maths TA levels ($ES_{\text{Orig}}=0.35$; $ES_{\text{Imputed}}=0.41$) than students from secondary schools characterised as inadequate in their overall attendance (see Table 5.12 and Table 5.13).

Additionally, students from secondary schools characterised as good or satisfactory on attendance made significantly greater progress in English and maths TA levels across KS3. The progress in science was significantly different only for students from secondary schools judged as good on attendance when compared to those attending inadequate secondary schools.

In summary, the results in this section highlight the relevance of the overall academic quality of the individual secondary school a student attends in promoting better academic progress during KS3 as well as predicting better levels of attainment (as demonstrated in Section 3.3.2).

In England, national DfE and Ofsted data sets provide overall indicators of school quality and these results indicate that students who attended a better secondary school (as measured by CVA scores and Ofsted judgements) benefited in terms of both their level of attainment in Year 9 and in making more progress across KS3.

5.3. Exploring the Effects of School and Teaching Processes on Academic Progress during KS3

The following factors that were tested as separate predictors of the Year 9 academic attainment were also tested in order to establish their significance in predicting students' academic progress during KS3 (see Section 4.1):

- Emphasis on learning
- Behaviour climate
- Headteacher
- School environment
- Valuing pupils
- School/Learning resources
- Teacher behavioural management
- Teacher support

For progress in each core curriculum subject, a number of the school factors were found to be statistically significant predictors of progress across KS3. Originally, the items that entered in the composition of any of the factors were Likert type scale that went from (1) strongly agree to (4) strongly disagree. These were reversed in order to make the interpretation easier. The factors were treated as continuous measures and were centred to the grand mean. Only the factors that were statistically significant predictors of academic progress are presented.

The academic progress in English was significantly predicted by 'emphasis on learning', 'behaviour climate', 'valuing pupils' and 'teacher support', although the effects sizes were weak and found to be significant mostly for the original sample (between 0.14 and 0.17 for the original sample or between 0.08 and 0.15 for the imputed sample). Students from secondary schools where they perceived a stronger emphasis on learning, a positive behaviour climate and teachers valuing the students and providing support to their students made significantly more progress in English during KS3. Interestingly, 'valuing pupils' and 'teacher support' were not statistically significant predictors of English TA levels; however, they were important and significant factors in predicting academic progress in English.

For the academic progress in maths during KS3, the following factors were found to be statistically significant: 'emphasis on learning', 'behaviour climate', 'headteacher', 'school environment', 'valuing pupils', 'school/learning resources' and 'teacher support' (see Table 5.19-Table 5.25). The ES ranged between 0.12 and 0.35 and most of them were statistically significant only for the original sample. Students from schools that were rated more positively for their 'emphasis on learning', provide a positive school 'behaviour climate', a pleasant environment and good 'learning resources' made more academic progress in maths than students from schools that were weaker in these dimensions. The factor measuring students' views of the leadership qualities of the headteacher was also found to be statistically significant predictor for academic progress in maths, which is an interesting finding as the same qualities did not predict academic attainment in maths. Students who perceived their headteacher as interested in what they learn and actively involved in the educational processes made more progress during KS3 than students who did not perceived their headteacher having these qualities. Similarly, the factor measuring students' views of teachers' supportive approach significantly predicted progress, although it had not been found to be a significant predictor of differences in attainment.

Students' academic progress in science was significantly predicted by 'emphasis on learning', 'behaviour climate', 'school environment', 'valuing pupils', 'learning resources', 'teacher discipline' and 'teacher support'. The ES were modest and statistically significant mostly for the original sample (between 0.14 and 0.21 for the original sample or between 0.04 and 0.10 for the imputed sample).

Students, who perceived that their secondary school placed a stronger 'emphasis on learning', provided a positive 'behaviour climate', a pleasant physical environment and good learning resources made significantly more progress in science during KS3. Moreover, students who perceived that their teachers value and support them also made significantly more progress in science. The factor related to 'teacher behavioural management' was also identified as a significant predictor of academic progress in science during KS3. This school factor was not significant in predicting Year 9 academic attainment in any of the subjects. These results suggest that while teachers' behaviours are not always statistically significantly associated with attainment, they may be more important in predicting academic progress.

5.3.1. Time Spent on Homework

As shown in section 4.2, students' self-reports of time spent on homework was positively linked to higher TA levels for all three subjects. Similarly, time spent on homework was a significant predictor of academic progress in the core subjects. For English and science, the relationship between time spent on homework and academic progress followed an incremental gradation up to 2-3 hours. Spending more than 3 hours on homework did not offer extra benefits for progress in English and science. The highest benefit of studying for 2-3 hours was found for maths ($ES_{\text{Orig}}=0.84$; $ES_{\text{Imputed}}=0.59$), followed by English ($ES_{\text{Orig}}=0.76$; $ES_{\text{Imputed}}=0.60$) and finally for science ($ES_{\text{Orig}}=0.69$; $ES_{\text{Imputed}}=0.47$). Studying for more than 3 hours significantly predicted better progress in English and maths, but only for the original data.

In the report, the primary to secondary transition was considered in terms of five dimensions that emerge from questionnaire responses (see Table 6.3). These dimensions appeared to summarise the most important aspects of the transition as perceived by students and parents. These five dimensions were:

1. Developing friendships, self-esteem and confidence
2. Settling into school life
3. Showing interest in school and work
4. Getting used to new routines
5. Experiencing curriculum continuity

Table 6.3: Underlying Dimensions of a Successful Transition Using Factor Analysis (N=550 children)

Underlying dimensions of a successful transition	
	Loadings
Developing friendships and confidence (1=less, 2=same, 3=more)	
1. Compared with Y6, child's school friends (source: parents)	0.403
2. Compared with Y6, child's self-esteem (source: parents)	0.868
3. Compared with Y6, child's confidence (source: parents)	0.881
4. Compared with Y6, child's motivation (source: parents)	0.564
<i>Cronbach's alpha= 0.839; Median= 2.5, SD= 0.52, N= 506</i> <i>1-2.5 = "0" (n = 266) versus 2.75-3 = "1" (n = 240)</i>	
Settling in school life (1=not at all to 4= very well/much)	
1. Child settling in (source: parents)	0.643
2. Satisfaction with the process of transition (source: parents)	0.475
3. Not having felt concerned about child when first moved on (source: parents)	0.471
4. Not feeling concerned about child now (source: parents)	0.774
5. Child settling in (source: children)	0.365
<i>Cronbach's alpha= 0.747; Median= 3.6, SD= 0.49, N= 485</i> <i>1.2-3.4 = "0" (n = 239) versus 3.6-4 = "1" (n = 246)</i>	
Showing a growing interest in school and work (1=less, 2=same, 3=more)	
1. Compared with Y6, child's interest in school (source: parents)	0.797
2. Compared with Y6, child's interest in school work (source: parents)	0.772
<i>Cronbach's alpha= 0.824; Median= 2.5, SD=0.56, N= 504</i> <i>1-2.5 = "0" (n = 295) versus 3 = "1" (n = 209)</i>	
Getting used to new routines (1=very difficult to 4= very easy)	
1. Having many different teachers (source: children)	0.740
2. Changing classrooms between lessons (source: children)	0.665
3. Behaviour and discipline (source: children)	0.472
4. Not being with same pupils in all lessons (source: children)	0.507
<i>Cronbach's alpha= 0.700; Median= 3.00, SD= 0.54, N= 490</i> <i>1-3="0" (n = 271) versus 3.25-4 = "1" (n = 219)</i>	
Experiencing curriculum continuity (1=not at all to 4 = very)	
1. English in Y6 helped cope with Y7 work (source: children)	0.762
2. Maths in Y6 helped cope with Y7 work (source: children)	0.580
3. Sciences in Y6 helped cope with Y7 work (source: children)	0.663
<i>Cronbach's alpha= 0.702; Median= 3.00, SD= 0.59, N=516</i> <i>1-3="0" (n = 276) versus 3.3-4 = "1" (n = 240)</i>	

In order to establish if there was a relationship between the primary to secondary school transition and KS3 outcomes, these dimensions were tested for their effects in multilevel models. Each dimension was considered individually in order to see which aspects of the transition had effects on KS3 outcomes.

Two sets of multilevel analyses were conducted. In the first set of multilevel models, a KS3 outcome was analysed for the effects of a transition dimension, controlling for all child, family, home, area and HLE characteristics. The main contextualised models predicting KS3 TA levels and identified with the original sample (N=3002) were extended to test the significant predictors on this subsample (N=550) (see Appendix for the complete models). In the second set of multilevel models, variables reflecting primary school and secondary school effectiveness were also included as predictors. This second set of analyses test whether transition dimensions influence KS3 outcomes independently of primary or secondary school characteristics.

The results of both sets of analyses were extremely similar, indicating that the transition dimension effects were largely independent of primary or secondary school effectiveness. The results that include control for primary and secondary school effectiveness are summarised here. Table 6.4 shows the results for the transition dimension 'getting used to new routines', and Table 6.5 shows

the results for the transition dimension ‘experiencing curriculum continuity’. In both cases, the relationships with all three KS3 academic outcomes are explored.

The results show that the transition dimensions, ‘getting used to new routines’, and ‘experiencing curriculum continuity’, both have significant effects on all three KS3 outcomes of English, maths and science. The effect sizes are all in the range 0.21 to 0.32, with the strongest effects for KS3 maths.

One other transition dimension, ‘settling into school life’, had a significant effect on KS3 maths only. However, this effect became non-significant when primary and secondary school effectiveness were controlled, indicating that this was not an independent transition effect. The remaining transition dimensions, ‘developing friendships, self-esteem and confidence’ and ‘showing interest in school and work’ appeared to be unrelated to KS3 academic outcomes.

Regarding academic progress, ‘getting used to new routines’ was a statistically significant positive predictor of academic progress in science during KS3 (see Table 6.6), while ‘experiencing

curriculum continuity' was a statistically significant positive predictor of academic progress in maths (see Table 6.7).

* $p < 0.05$

In summary it appears that having a successful primary to secondary school transition can improve KS3 outcomes 3 years later and academic progress. In particular the aspects of the transition included in the dimensions, 'getting used to new routines', and 'experiencing curriculum continuity' seem to be most important.

7. The Impact of Primary School Mobility During KS1 and KS2

The present analyses explored the relationships between mobility during KS1 and KS2 in primary school and students' later academic outcomes in KS3. The results are presented only on the original data set. It should be noted that no measures are available for students' mobility in secondary school across KS3.

We adopted the definition of student mobility used in previous reports when the EPPSE sample was in primary school. In this definition, mobility referred to a change of primary school that did not result from a school closure, amalgamation, or transfer across phases of schooling. For the original sample (n=3002), we combined the two measures of mobility for a change of primary school between KS1, KS2 and mobility in terms of a change of primary school between KS1 and KS2. More than 11% of the students had moved primary school only in KS1, while almost 16% moved only in KS2. In total nearly 4% of students had moved primary schools in both KS1 and KS2 (see Table 7.1).

Table 7.1: Mobility During KS1 and KS2

	n	%
Missing	34	1.1
No mobility at all	1887	62.9
Mobility only in KS1	340	11.3
Mobility only in KS2	474	15.8
Mobility in both	109	3.6
Moved between KS1 and KS2	158	5.3
Total	3002	100

Previous analyses showed that moving primary schools in either KS1 or KS2 was related to the level of social (dis)advantage; students from disadvantaged families being more likely to move primary schools (Melhuish et al., 2008b).

Table 7.2 and

Table 7.3 present the cross-tabulations between mobility and multiple disadvantage³² at various time points. Students who had a more disadvantaged background were more likely to move primary schools during KS1 and KS2. However, the associations between mobility and multiple disadvantage were not statistically significant.

Table 7.2: Mobility During KS1 and Multiple Disadvantage Index

Multiple disadvantage	Mobility during KS1					
	Non-mobile		Mobile		Total	
	n	n	n	n	n	n
0 (no disadvantage)	543	86.5%	85	13.5%	628	100.0%
1	647	86.3%	103	13.7%	750	100.0%
2	492	84.1%	93	15.9%	585	100.0%
3	306	82.0%	67	18.0%	373	100.0%
4	207	86.3%	33	13.8%	240	100.0%
5 plus (high disadvantage)	159	82.4%	34	17.6%	193	100.0%
Total	2354	85.0%	415	15.0%	2769	100.0%

³² The Multiple Disadvantage index is a single measure combining ten different variables (from the child, parent, and home level, each of which has been shown to be an indicator of 'risk' of poor educational outcomes (Sammons et al., 2004d).

Table 7.3: Mobility During KS1 and Multiple Disadvantage Index

Multiple Disadvantage	Mobility during KS2					
	Non-mobile		Mobile		Total	
	n	%	n	%	n	%
0 (no disadvantage)	508	82.6%	107	17.4%	615	100.0%
1	586	79.9%	147	20.1%	733	100.0%
2	462	80.5%	112	19.5%	574	100.0%
3	277	76.7%	84	23.3%	361	100.0%
4	175	78.1%	49	21.9%	224	100.0%
5 plus (high disadvantage)	147	77.8%	42	22.2%	189	100.0%
Total	2155	79.9%	541	20.1%	2696	100.0%

When exploring the relationship between KS1-KS2 mobility and academic outcomes in KS3, we found that mobility during KS2 was a negative predictor of Year 9 TA levels in English, maths and science (see Table 7.4, Table 7.5, Table 7.6). Students who had changed primary school only during KS2 obtained lower levels of Year 9 TA in all three core areas of the curriculum English, maths and science, even when the analyses controlled for the influence of a range of student and family background characteristics, HLE, neighbourhood disadvantage and school level FSM. Additionally, for maths, mobility during KS1 was also found to be a negative predictor of lower levels of TA in Year 9. Students who had moved primary schools during KS1 obtained significantly lower levels of TA in maths in Year 9 than students who had not moved at all.

In interpreting these results we note that the ES are relatively modest (in the order of ES 0.18 for maths, ES 0.14 for English and ES 0.15 for science for mobility in KS2 versus no change of primary school).

It is possible that a disruption to educational experiences occasioned by a change of primary school unsettles students and affects their attainment. Alternatively, it may be that the change of schools is related to an unsettling life event (e.g., parental divorce, re-partnering/marriage, change of occupation/unemployment) or some combination of the two. It may also be the case that some changes of school are linked to or reflect difficulties a child has in their primary schooling (e.g., a response to bullying, lack of friends or parents' concerns over educational standards). We thus cannot attribute causality to the relationship we have identified but rather can conclude that mobility during the primary school period tends to predict poorer academic outcomes in secondary school and thus can be viewed as a potential risk factor.

7.1. The Impact of Combined Terms of Mobility and FSM on KS3 Outcomes

The combined terms of primary school mobility (i.e., any mobility in KS1, KS2 or between KS1 and KS2) and Year 6 FSM were created and tested in contextualised models that controlled for the influence of a range of student and family background characteristics, HLE, neighbourhood disadvantage and school level FSM. The results showed that students who were eligible for FSM and moved primary schools in KS1 and/or KS2 obtained lower levels of TA in all three KS3 outcomes. However, the effect of mobility on students with FSM is more evident on the results in Maths and Science (see Table 7.7).

8. Summary and Conclusions

This report provides a detailed investigation of the academic attainments of the EPPSE sample of students at the end of KS3. It builds on earlier research that has followed this group from early childhood at age 3 years through primary school and into secondary school up to age 14.

Previously the project has demonstrated that a range of factors related to child and family characteristics and the home learning environment are important predictors of children's academic attainments and progress up to the end of primary school (Sammons et al., 2008a; Sylva et al., 2010). The impact of these influences can be detected from a young age and can also affect later educational attainment. The variations in achievement point to the negative effects of socio-economic disadvantage and the results of the research have contributed to policy developments in England associated with issues of equity and social inclusion (see The Equalities Review, 2007).

This current follow up of the sample in adolescence (Year 9 age 14) provides new evidence about the size of the equity gap in attainment as measured by teachers' judgements of student attainment in the three 'core' curriculum areas of English, maths and science (reflected by differences in TA levels).

In contrast to earlier research on this sample (during KS2), it was not possible to study variations in students' KS3 attainment using national assessment test scores as outcomes, due to a change in education policy. Instead, the analyses presented in this report are based on TA judgements that are less finely differentiated than test scores and tend to reflect greater subjective bias due to possible 'halo effects' (see Bew, 2011; Harlen, 2004). However, teacher judgements of attainment in Year 9 is likely to play an important role in shaping students' future educational decisions and subject choices in KS4 and therefore, can be viewed as important measures of educational outcomes to investigate.

The analyses in this report identify which child, family and home learning factors predict EPPSE students' KS3 outcomes. The results show similarities to earlier findings for this sample. A brief summary of the main findings is presented. While many results on the impact of gender, parents' qualifications or SES are in accord with those from other educational research studies, EPPSE also reveals the continued importance of the early years Home Learning Environment (HLE). The EPPSE project is unique in its exploration of the influence of this factor across different phases of students' education and has identified the way that the early years HLE continues to predict attainment up to age 14. In addition, the latest research discussed in this report demonstrates that various family background factors continue to influence students' academic progress across KS3. It should be noted that in the progress analyses, prior attainment in national assessment tests taken at the end of primary education (Year 6, KS2) was used included as a baseline in the statistical models.

This report focuses on statistical trends and quantitative analyses of factors that predict attainment and progress in KS3 based on results using multilevel statistical models. Elsewhere, EPPSE has reported (in keeping with the mixed methods research design involving both quantitative and qualitative approaches) findings from qualitative case studies of children and families that are more educationally successful in overcoming disadvantage (see Siraj-Blatchford et al., 2011). The qualitative data helps to provide a broader understanding of the way social disadvantage shapes students' educational outcomes and experiences at different ages and what factors help to protect against the adverse consequences of disadvantage.

As well as investigating the impact of child, family and HLE background, the EPPSE research has explored the continued influence of pre-school and primary school as predictors of students' later attainment at age 14 and also tested a range of measures related to secondary school experiences. The results, therefore, provide new evidence on the way different educational settings (pre-school, primary and secondary school) affect attainment and progress in KS3.

In order to maximise the sample size in our analyses, multiple imputation of missing data was used. Careful comparison of the results from both imputed and non imputed data sets were conducted and indicate that the results are robust producing very similar and the patterns consistent.

Raw Differences in Attainment for Different Student Groups

Overall, EPPSE students' had higher average attainments in maths than in either science or English (a difference of around 0.5 of a national curriculum level comparing maths and English, and 0.36 of a level comparing maths and science) at the end of KS3. This pattern of higher results in maths is in line with the most recent international TIMSS survey (Martin et al., 2008; Mullis et al., 2008; Sturman et al., 2008) of maths and science achievement that revealed England as the highest performing country in Europe in maths with the most improved results since 1995. It is likely that this improvement is linked with the introduction of the National Numeracy Strategy in 1998 (DfEE, 1998). In interpreting the KS3 results, it should be noted that EPPSE students had experienced the numeracy strategy in their primary education.

Gender

In Year 9, girls had higher attainment in terms of average TA English results than boys by around 0.4 of a national curriculum level (approximately half a standard deviation in size), but there were no significant gender differences in maths or science results. At younger ages, girls had been shown to have higher attainment in Reading and English and there were also smaller differences in maths and science outcomes in primary school but by age 14 these differences have disappeared.

Ethnicity

There was some evidence of ethnic differences in attainment but due to low numbers for most groups in the EPPSE sample the results should be interpreted with caution. Nonetheless, the differences found in average results by ethnic group are in line with those evident in other studies indicating higher attainment for some groups e.g. Indian and lower for others e.g. those from Pakistani heritage.

Family Characteristics

There were marked differences in attainment related to parents' qualification levels. As might be anticipated, students with highly qualified parents (degree level) had much higher attainment on average than those students whose parents had no qualification (the difference was equivalent to 1.4 TA levels for English, 1.7 for maths and 1.5 for science).

There were similarly large differences related to family socio-economic status (SES) between those from professional non-manual and those from lower SES categories. Moreover, students eligible for Free School Meals (FSM) had lower average attainment than students who were not eligible for FSM. The differences were around 0.7 and 0.8 of a national curriculum level in each subject.

Differences in the Early Years HLE were also associated with later differences in average attainment Year 9. The difference for English and science was approximately 1 national curriculum level, for maths it was 1.3 of a level for those of high versus low scores.

The Net Impact of Child, Family and HLE Factors on Attainment in Year 9

The average group differences described above do not take into account the relative influence of other characteristics. Multilevel modelling provides more detailed results of the 'net' contribution of individual factors, whilst controlling for other predictors and so enables the identification of the 'strongest' net predictors. For instance, we show the higher attainment in students with mothers who have degrees compared to those with no qualifications, net of the influence of other family and child factors (SES, income, HLE or gender).

Our findings are summarised in Table 8.1.

[†] The number of EPPSE students in minority ethnic group categories is typically small. Thus, any differences for specific groups must be interpreted with caution.

*The reference group for all pre-school quality and effectiveness comparisons is the 'home' group, who had very little or no pre-school experience. The effect sizes represent differences between the 'home' group and the 'high quality/effectiveness' group unless stated otherwise.

** The reference group for primary school is 'low effectiveness'. The effect sizes represent differences between the 'low effectiveness' group and the 'high effectiveness' group.

Mother's qualification level was the strongest predictor of better attainment for English, maths and science. The next strongest predictor was gender but for English only, where the effect was larger in KS3 than was the case when these students were in primary school.

There were also a number of additional strong/moderately strong predictors as follows for:

English: family income, birth weight, father's highest qualification level, and the Early Years HLE;

Maths: birth weight, Early Years HLE, father's qualification level, ethnicity and family SES;

Science: father's qualification level, Early Years HLE, family SES and ethnicity.

It should be noted that ethnicity was not a significant predictor of TA levels in English, but it was for maths and science; students of Indian heritage obtained significantly better results in maths and science than White British students. Both FSM (the low income indicator) and family SES also have moderate effects on English, maths and science. These effects were similar in size to the effects of the Early Years and KS1 HLE for English. The Early Years HLE had a stronger impact on students' KS3 maths and science attainment than the low income indicator FSM.

Older students (for their age group e.g. Autumn born) also showed better results though the effect was not strong. There were also small positive effects related to the age of the child's mother (at birth); the older the mother then the better the outcomes, compared to children of younger mothers.

There is evidence that the 'social composition' of the school (as measured by the percentage of students entitled to free school meals, an indicator of poverty) can affect individual student's outcomes over and above their own FSM status. EPPSE students who attended a secondary school with higher proportions of students receiving FSM showed poorer attainment in English, maths and science, although the effects were relatively weak.

These results broadly confirm patterns identified at younger ages indicating that differences in attainment related to individual student and family background influences emerge early (at age 3) and remain fairly stable as students progress through primary and secondary school. The results supporting this conclusion are well established in previous social and educational research.

Neighbourhood Influences

A number of neighbourhood measures were tested as potential predictors of students' KS3 academic attainments. Previous research has suggested that contextual influences outside the family (such as school and neighbourhood composition) may influence student attainment. Living in a disadvantaged area and attending a school with a higher representation of disadvantaged students, may affect student and family aspirations and attitudes to education and also teacher expectations.

The DfE's national Contextual Value Added (CVA) measure of school performance has demonstrated that the school measure (percentage of FSM students) and neighbourhood measures such as the IMD and IDACI score predict student progress. As noted above the percentage of students on FSM in a secondary school also predicted attainment for the EPPSE sample.

Levels of neighbourhood disadvantage (measured by the IMD - Noble et al., 2004; and IDACI - Noble et al., 2008) were also significant predictors of lower student attainment in English and science in Year 9. This was not the case during the primary school years, possibly because neighbourhood influences increase as adolescents interact more with their peer group outside the home. Students who live in disadvantaged neighbourhoods had poorer attainment, over and above their own and their family characteristics, although these neighbourhood effects are relatively small compared to those of the family.

Other neighbourhood measures were also obtained by the EPPSE research. These included the level of employment and the percentage of residents with limiting long term illnesses, but neither of these was found to predict students' attainment. In contrast, the percentage of the population who were classed as White British was statistically significant with small negative effects for each

subject. The level of crime recorded in a neighbourhood was also found to have small negative effects on attainment and progress in English and science. Similarly, parents' perceptions of the safety of their neighbourhood also showed small positive effects on attainment (maths and science) and progress (science).

Taken together the results indicate attainment was lower for students who lived in more disadvantaged neighbourhoods compared to those in more advantaged neighbourhoods, over and above their own and their family characteristics. The neighbourhood influence though relatively small seems to have become stronger in as the EPPSE sample go through early adolescence.

Pre-school

The EPPSE research was designed to follow up children recruited at pre-school into primary and later secondary school in order to identify and investigate the contribution of different educational influences on their later progress and development in different phases of education. In addition to investigating individual student, family, home learning and neighbourhood, further analyses sought to establish whether pre-school influences identified as significant predictors of attainment and progress in both cognitive and social behavioural outcomes at younger ages still show effects nine years later when the variation in attainment is studied up to age 14 years.

Three measures were tested: whether or not the student had **attended** a pre-school (a comparison with the 'home' group); the **quality** of the pre-school attended (as measured by the ECERS-R and E environmental rating scale instruments) and the **effectiveness** of the pre-school attended.

Attendance

Just having attended a pre-school was found to be a statistically significant predictor of better attainment in both maths and science (but not English) at the end of KS3, compared with the 'home' group. Although relatively weak ($ES=0.26$ for maths and $ES=0.22$ for science), these effects were still stronger than those found for 'age' (being Autumn born) and similar to the effect for family income (in both maths and science).

Quality

The quality of pre-school also continued to predict better outcomes in maths and science nine years after leaving pre-school. The effects of medium and high quality were slightly larger than for low quality (compared to 'home' group). For example, the ES for high quality was 0.28 for maths. In science, only those who had attended a medium or high quality pre-school continued to show significantly better attainment than the home group in TA levels at age 14.

Effectiveness

The indicator of pre-school effectiveness in promoting pre-reading skills continued to predict better outcomes in English in lower secondary school. However, only the highly effective category was statistically significant ($ES=0.20$) in predicting better attainment when compared to the 'home' group.

For maths, all groups ($ES=0.36$ for high; $ES=0.22$ for medium; and $ES=0.30$ for low effectiveness) had significantly better results than the 'home' group after controlling for other factors. For science, attending a high ($ES=0.33$) or medium effective ($ES=0.19$) pre-school (in promoting early number concepts) predicted significantly better outcomes than not attending a pre-school. Those attending a low effective pre-school showed no better outcomes in science by the end of KS3 than the 'home' group.

Primary School Influence

Previous EPPSE research has shown that the academic effectiveness of a child's primary school is a statistically significant predictor of better attainment and progress across KS2 for English and more strongly for maths. Other educational effectiveness research has shown that primary schools can continue to influence students' longer term academic outcomes at secondary school (Goldstein & Sammons, 1997; Leckie, 2009). Measures of the academic effectiveness² in English and maths of the primary school attended by the EPPSE students were explored to see whether they had a

positive influence on later attainment at the end of KS3. The KS3 analyses reveal that the academic effectiveness of the primary school the EPPSE students had attended still predicted better outcomes for both maths and science attainment three years after transferring to secondary school.

Controlling for student, family and HLE background characteristics, by the end of KS3, the extra benefit of attending a medium effective primary school was relatively small compared with the low effective group ($ES=0.13$ for maths). The net effects of attending a high academic effective primary school on later attainment compared with the effects of attending a low effective one were rather stronger ($ES=0.31$ for maths & 0.29 for science). The effects are similar in size to those attributable to FSM. The effect in terms of TA levels is a third of a level for maths and a quarter of a level for science.

Combined effects of phases of education

Pre-school and HLE

Further analyses also explored joint effects of pre-school and the Early Years HLE. The results showed that those with a low Early Years HLE obtained better outcomes in terms of later English, maths and science if they had attended a pre-school. The net differences were equivalent to between 0.4 and 0.7 of a national curriculum level ($ES=0.37$ for English; $ES=0.56$ for maths and $ES=0.48$ for science).

The quality of the pre-school measured by ECERS-E no longer showed differences in relation to students' Early Years HLE for English, maths or science in Year 9, in contrast to findings from the primary school.

There was an indication that the effectiveness of the pre-school in promoting early number concepts mattered in the study of joint effects for later science in Year 9. Here for both the low and the high HLE group there was evidence of a trend. Those with a low Early Years HLE showed particular benefits if they had previously attended a high effective pre-school ($ES=0.61$) showing similar results in terms of boost to those who had a medium or high HLE who had not attended pre-school. These results again suggest that high effective pre-school experience may have some compensatory benefits in promoting better later academic outcomes in science up to age 14.

Primary-school effectiveness and parent's qualification level

Further analyses explored joint effects for different student groups. For students whose parents had low educational qualifications, the boost in maths predicted from attending a high effective primary school compared with a low effective one was also larger (difference in $ES=0.33$) than the boost provided for students of parents with higher qualification levels (difference in $ES=0.17$). A similar pattern of results was found for science Year 9 TA levels. This suggests some continuing compensatory impact of previous attendance of a more academically effective primary school for students whose parents have lower educational qualifications.

Primary school and pre-school

The joint effects of pre-school quality and the primary school effectiveness were also investigated. These also pointed to the continued benefits of primary school academic effectiveness even when pre-school effects are taken into account for both maths and science outcomes in Year 9.

Pre-school effectiveness (in promoting early number concepts) was tested jointly with the primary school academic effectiveness measure and the results indicated that attending a high effective pre-school offered some protective effects (even if a student went on to a less effective primary school) for later maths and science outcomes. Likewise, having attended a more academically effective primary school mitigated the effects of experiencing no or only a low effective pre-school. The longer term protective effects of pre-school effectiveness were shown most clearly for students who then attended a low academically effective primary school when we studied their later attainment in Year 9 of secondary school.

Secondary and pre-school effectiveness

Further analyses of the combined effects showed that the continued benefits of pre-school were most evident for EPPSE students who went on to attend medium or low effective secondary schools, suggesting a protective influence of pre-school against attending an ineffective secondary school.

Transition from Primary to Secondary School

A subsample of approximately 550 EPPSE students and parents were asked about their personal experiences and views related to the transition from primary to secondary school, including their settling down in the new school, the academic work, their friendships and things that primary/secondary schools did to assist or smooth the transition. Five factors were identified to be deemed salient in the transition (Evangelou et al., 2008 for full details):

- Developing friendship, self-esteem and confidence
- Settling into school life
- Showing interest in school and schoolwork
- Getting used to new routines
- Experiencing curriculum continuity

EPPSE examined the importance of the transition experience on subsequent achievement and found that, those students who settled quickly into school routines and who experienced continuity in the curriculum from primary to secondary school made better progress in maths and science across KS3 and also had higher attainment in all three core subjects at Year 9. Although statistically significant, these effects were relatively small (ES range between 0.21 and 0.32). Other transition factors were less predictive of school-success, suggesting that familiarity with the school building and routines, along with familiar curriculum materials in lessons were more important during transition than the psychological dimensions of self-esteem and confidence or the social dimension of settling into school (social) life.

Primary School Mobility

The present report also explored the relationships between mobility during KS1 and KS2 in primary school and students' later academic outcomes in KS3. Results showed that mobility during KS2 was a negative predictor of Year 9 TA levels in English, maths and science. Students who had changed primary school only during KS2 obtained lower levels of Year 9 TA in all three core areas of the curriculum English, maths and science, even when the analyses controlled for the influence of a range of student and family background characteristics, HLE, neighbourhood disadvantage and school level FSM. Additionally, for maths, mobility during KS1 was also found to be a negative predictor of lower levels of TA in Year 9. Students who had moved primary schools during KS1 obtained significantly lower levels of TA in maths in Year 9 than students who had not moved at all.

Overall, these analyses of EPPSE students' attainment in English, maths and science in Year 9 has provided a wide range of evidence concerning the factors that predict attainment in Year 9 as measured by TAs, and also progress across KS3.

Secondary School Influences

We tested the academic effectiveness of secondary schools using CVA measures derived from the DfE's National Pupil Database. These measures show the relative progress made by student intakes measured from KS2 to KS4 (across 5 years). In contrast to our primary school academic effectiveness measure that examined results in English, maths and science separately (Melhuish et al., 2006a; 2006b), we did not have subject specific results for these secondary school CVA indicators. The secondary school CVA measure of effectiveness did not predict EPSSE students' differences in attainment in Year 9, after controlling for individual student, family and HLE measures.

However, after controlling for the same characteristics, the quality of secondary school measured by Ofsted inspection ratings on the 'quality of students' learning' was a statistically significant predictor of attainment in both English and science, with the difference being only statistically significant (but

moderately strong) for the 'outstanding' schools category compared with the 'inadequate' category (ES= 0.42 English, ES=0.51 science).

For maths, schools judged by Ofsted as 'good' (on quality of learning) showed more modest but significant positive effects (ES=0.26) and those judged as 'outstanding' showed stronger effects (ES=0.56) compared with the 'inadequate' category.

These results support the hypothesis that secondary school quality remains important in shaping students' academic attainment, over and above the impact of background factors. The effects are equivalent to between 0.34 and 0.64 of a TA level for those who attended an 'outstanding' rather than an 'inadequate' school (in terms of the Ofsted judgement 'quality of learning'). A similar strong pattern was identified for Ofsted judgements of learners' attendance. It should be noted that these two Ofsted measures (quality of learning and learners attendance) are also correlated.

Students' Progress across Key Stage 3

Students' academic progress across KS3 was studied by controlling for the prior attainment at the end of primary school and taking account of individual student, family and HLE factors. Fewer background factors predicted progress across KS3 than were significant for attainment. The patterns were similar to those found to be at younger ages when we studied students' progress across KS2 for this sample.

Overall, there was evidence that students (see Table 8.2):

- older for their year group (Autumn born) (ES=0.24-English, ES=0.32-maths and ES=0.20-science),
 - girls (ES=0.32-English, ES=0.16-maths and ES=0.17-science),
 - with highly qualified fathers (ES=0.28-English, ES=0.28-maths and ES=0.43-science),
- made more progress in English, maths and science over KS3.

Students whose mothers were highly qualified (degree/higher degree) made better progress in English (ES=0.34) and science (ES=0.33). Additionally, students whose families had high incomes also made better progress in English (ES=0.39). There were small negative effects related to early behavioural problems, and eligibility for FSM.

A higher percentage of students in a school eligible for FSM predicted poorer progress for the EPPSE sample in both English (ES=0.18) and science (ES=0.21). Of the neighbourhood measures tested, only the percentage of White British and the level of reported crime were significant predictors of poorer student progress in English. For progress in science however, reported crime, perceived neighbour safety, the IMD and IDACI were statistically significant predictors. These findings indicate that the disadvantage of the school's intake and students' neighbourhood characteristics had small negative effects predicting both poorer progress and attainment and shows that schools in some areas face more challenging circumstances in improving student learning outcomes.

Neither the pre-school measures nor the primary school academic effectiveness measure were significant predictors of students' progress in KS3. However, the secondary school overall academic effectiveness indicator was found to be a statistically significant predictor for progress in English.

Higher Ofsted measures of the 'quality of students' learning' and 'attendance of learners' also proved to be significant predictors of better progress in all three core subjects. EPPSE students who attended an 'outstanding' secondary school in terms of the 'quality of learning' made significantly more progress in the three core subjects than those in schools judged to be 'inadequate' (ES ranged between 0.29 and 0.36). Additionally, students from secondary schools characterised as 'outstanding', 'good' or even 'satisfactory' in terms of 'students' attendance' made significantly more progress in English (ES=0.48 for outstanding) and maths (ES=0.35 for outstanding). These findings provide some evidence of external validity for the use of Ofsted inspection judgements and are in

line with earlier results on a sub-set of primary schools investigated as part of the EPPE 3-11 phase of the research (Sammons et al., 2008c).

Table 8.2: Summary of Background Characteristics on Academic Progress

(Only the largest effect sizes for the original data are reported; comparison group in brackets)

	English	Maths	Science

Students' experiences and views of secondary school

Students' secondary school experiences were measured using self-report questionnaires administered in Year 9. Various measures of school experiences were identified and tested to see if they predicted variations in students' KS3 academic attainment and progress after control for individual, family and HLE factors, including the percentage of students on FSM in the school.

The results indicate that students who perceived their school to place higher 'emphasis on learning' had significantly higher attainment. The difference was between half in English and science to three quarters of a TA level for maths (ES ranged between 0.20 and 0.22).

EPPSE students' attainment was also found to be higher where they perceived a more positive 'behaviour climate' in their secondary school. The difference was particularly noticeable for maths (ES=0.46). The perceived 'quality of their school environment'³³ was also a predictor of better attainment, although the effects were smaller and only significant for maths and science (ES=0.13 for both). Similar, small but positive effects were identified for the factor related to students' perceptions of how much they felt teachers' valued and respected them. Finally, the factor 'learning resources' (related to whether students felt the school was well equipped with computers and technology) also predicted better attainment in maths (ES=0.13) and science (ES=0.15) in KS3. Although the effect sizes are relatively small, this is the equivalent of around half a TA level for both these subjects.

After testing these factors separately as predictors of attainment, we also tested them together to investigate which ones are the most important in predicting academic outcomes in Year 9 when still controlling for individual student, familial and HLE characteristics. . For all three core curriculum subjects, it was found that the two factors 'emphasis on learning' and 'behaviour climate' together significantly predicted Year 9 academic attainment.

³³ This factor includes attractive and well decorated buildings, cleanliness of toilets etc.

Looking only at students' progress during KS3 'behaviour climate', 'valuing pupils' and 'teacher support' were significant predictors of progress in English, maths and science. 'School environment and 'learning resources' were only significant for maths and science. 'Headteacher qualities' was a significant predictor for progress in maths (ES=0.15). Finally, 'teacher behaviour management' was a significant predictor of progress in science (ES=0.14).

After control for individual, family and HLE influences, the daily time spent on homework, as reported by students, was found to be an important and strong predictor of better attainment and progress. The strongest effects were noted for those who reported 2-3 hours per day. For attainment in English this had an ES of 0.73 (equivalent to 0.6 of a TA level). For attainment in maths, the ES was 0.84 (equivalent to almost 1 TA level) similar to the effects for science (ES 0.85, equivalent to nearly 0.75 of a level). For academic progress in the three core subjects, the ES for 2-3 hours of homework/day ranged between 0.69 and 0.84. Spending more time on homework is likely to increase study skills and opportunities to learn, it may also be influenced by self-regulation. It is also likely to reflect secondary school policies and teacher expectations and the academic emphasis in the school as well as encouragement from parents to take school work seriously.

Students' views of themselves

Earlier EPPSE research (Sammons et al., 2008d) has shown positive relationships exist between academic self-concept and attainment. Higher academic self-concept predicts better attainment and vice versa. Patterns of attainment and self-concept in younger children can shape their future identities as learners. The results for EPPSE students in secondary school show fairly strong links between academic self-concept in maths as a predictor of attainment in Year 9 (ES=1.2; nearly 1 TA level). By contrast, academic self-concept in English was a weaker predictor of Year 9 English attainment (ES=0.74; equivalent to approximately a half of a TA level). Students' self-reported enjoyment of school, also predicted attainment, with stronger effects for maths (ES=0.38 maths; ES=0.31 science; ES=0.29 English).

The Pre-school phase:

End of pre-school phase report and research brief

Final report of the pre-school phase: <http://www.education.gov.uk/publications/eOrderingDownload/SSU-FR-2004-01.pdf>

Research brief on the pre-school phase:

<http://www.education.gov.uk/publications/eOrderingDownload/SSU-SF-2004-01.pdf>

There are twelve technical papers associated with this phase of the research - see <http://eppe.ioe.ac.uk>

Technical Paper 1 (1999)

An Introduction to the Effective Provision of Pre-School Education (EPPE) Project.

Technical Paper 2 (1999)

Characteristics of the Effective Provision of Pre-School (EPPE Project sample at entry to the study.

Technical Paper 3 (1999)

Contextualising EPPE: Interviews with local authority co-ordinators and manager.

Technical Paper 4 (1999)

Parent, family and child characteristics in relation to type of pre-school and socio-economic differences.

Technical Paper 5 (2000)

Characteristics of the centres in the EPPE sample: Interviews.

Technical Paper 6 (1999)

Characteristics of the centres in the EPPE sample: Observation profiles.

Technical Paper 6A (1999)

Characteristics of pre-school environments.

Technical Paper 7 (2001)

Social-behavioural and cognitive development at 3-4 years in relation to family background.

Technical Paper 8a (2002)

Measuring the impact of pre-school on children's cognitive progress over the pre-school period.

Technical Paper 8b (2003)

Measuring the impact of pre-school on children's social-behavioural development over the pre-school period.

Technical Paper 9 (2004)

Report on age 6 assessments.

Technical Paper 10 (2003)

Intensive case studies of practice across the Foundation Stage.

Intensive case studies of practice across the Foundation Stage. Research Brief No RBX16-03

Technical Paper 11 (2004)

Report on the continuing effects of pre-school education at age 7

Technical Paper 12 (2004)

The final report

Pre-school pedagogy

Researching Effective Pedagogy in the Early Years (REPEY - 2002): Research Report 356

<http://www.education.gov.uk/publications/eOrderingDownload/RR356.pdf>

The Primary Phase:

End of primary school phase report and research brief

Final report from the primary phase: Pre-school, school and family influences on children's development during Key Stage 2 (2008). Research Report RR061

Appendix 5: Early Years, KS1 and KS2 Home Learning Environment

The Early Years Home Learning Environment (HLE)

The EPPE Project - Students' activities at home

Does X have?

A regular bedtime

Rules about watching TV/videos

How often does X watch TV/videos in a typical weekday?

How many days in a typical week has X?

Played with friends at home

Does X have friends home to play?

Played with friends elsewhere

Does s/he go anywhere else to play?

Gone shopping with you

Gone on visits to friends or relatives

Sat down and eaten a meal with the whole family together

Does anyone at home ever read to X? If yes, how often?

Does anyone at home ever take X to the library? How often?

Does X ever play with letters or numbers? How often?

Does X ever paint and draw at home? How often?

Have you ever tried to teach X? ABC/ The Alphabet/ letters?

Numbers? How often?

Any songs/poems? How often?

Can you tell me which?

Any nursery rhymes? How often?

Can you tell me which?

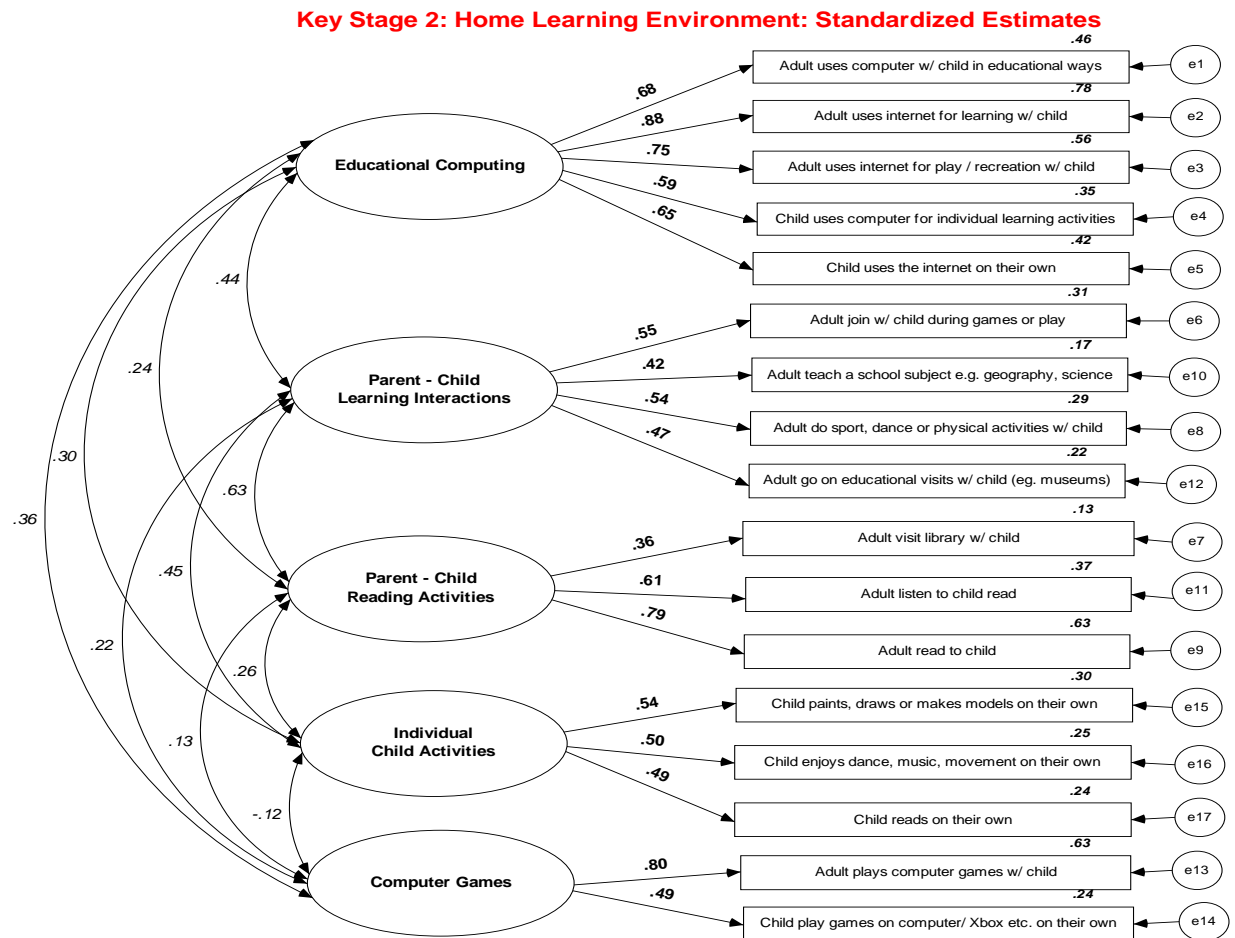

The Key Stage 1 Home Learning Environment (HLE)

KS1 HLE Factors and the items loading on these factor:

- **Home Computing**
 - The Child plays on computer by themselves.
 - Respondent plays computer games with the child.
 - Respondent uses computer with the child in educational ways.
- **Parent-Child Enrichment outings/activity outside home.**
 - Respondent visits library with the child.
 - Respondent does sport/physical activity with the child.
 - Respondent goes on educational visits with the child.
- **Parent-child one-to-one interactions at home**
 - Respondent plays with the child using toys/games/puzzles.
 - Respondent reads to the child.
 - Respondent listens to the child read.
- **Expressive play**
 - The Child plays 'make believe' or pretend games.
 - The Child paints/draws/makes models.
 - The Child enjoys dance music and movement.

The Key Stage 2 Home Learning Environment (HLE)

KS2 HLE Factors and the items loading on these factor:

Appendix 6: Results of Contextualised Multilevel Analyses

Table A.6.1: Contextualised Models for English Teacher Assessment Levels in Year 9 (Original Data vs. Imputed Data)

Appendix 8: Details of Factor Composition- Schools and Teaching Processes and Students' Views of Themselves

Table A.8.1: The Final Factor Structure Views of School

Teacher support	Cronbachs =0.86	School environment	Cronbachs =0.75
Most teachers mark and return my homework promptly		My school has attractive buildings	
Most teachers make helpful comments on my work		Classrooms are nicely decorated and clean	
Teachers praise me when I work hard		Toilets are well cared for and clean	
Teachers tell me how to make my work better		My school is well organised	
Teachers make me feel confident about my work		People think my school is a good school	
Teachers are available to talk to me privately			
Teachers will help me if I ask for help			
I get rewarded for good behaviour			
Headteacher qualities	Cronbachs =0.72	Behaviour climate	Cronbachs=0.72
I often see the headteacher around the school		Most pupils want to leave this school as soon as they can	
The headteacher makes sure pupils behave well		Pupils who work hard are given a hard time by others	
The headteacher is interested in how much we learn		Most pupils take no notice of school rules	
		There are often fights (in or around school)	
		Some kids bring knives or weapons into school	
Teacher behavioural management	Cronbachs =0.62	Learning resources	Cronbachs=0.70
Teachers make sure that it is quiet during lessons		There are enough computers	
Teachers make clear how I should behave		Science labs are good	
Teachers take action when rules are broken		We have a good library	
Teachers are not bothered if pupils turn up late		We get enough time using computers in subject lessons	
Valuing pupils	Cronbachs=0.78	Emphasis on learning	Cronbachs=0.68
The school values pupils' views		Most pupils want to do well in exams	
Teachers listen to what pupils say about the school		Teachers expect me to do my best	
The teachers in this school show respect for all pupils		The lessons are usually 'challenging' but 'do-able'	
Teachers are unpleasant if I make mistakes		Most teachers want me to understand something, not just memorise it	
Teachers are friendly towards me		Most teachers believe that mistakes are OK so long as we learn	

Table A.8.2: The Final Factor Structure for Views of Self

Maths academic self image	Cronbachs =0.91	English academic self image	Cronbachs =0.90
I learn things quickly in my Maths classes		I learn things quickly in my English classes	
I have always done well in my Maths classes		I have always done well in my English classes	
Compared to others my age I am good at Maths		Compared to others my age I am good at English	
Work in my Maths classes is easy for me		Work in my English classes is easy for me	
I get good marks in Maths		I get good marks in English	
Values	Cronbachs=0.75	Popularity	Cronbachs =0.83
Making sure strong people don't pick on weak people		I make friends easily	
Respecting rules and laws		Other teenagers want me to be their friend	
Controlling your temper even when you feel angry		I have more friends than most other teenagers my age	
Respecting other peoples points of view		Most other teenagers like me	
Sorting out disagreements without fighting		I am popular with other pupils in my pupils in my age group	
Anxiety	Cronbachs=0.78	Enjoyment of school	Cronbachs=0.74
In class I worry about what the others think of me		My school is a friendly place	
I get a lot of headaches, stomach aches or sickness		On the whole I like being at school	
I worry a lot		I like to answer questions in class	
I am often unhappy, downhearted or tearful		School is a waste of time for me	
I am nervous in new situations		I like most of the lessons	
I have many fears, I am easily scared		I am bored in lessons	

Appendix 9: Tested Ofsted Inspection Judgements

Several Ofsted inspection judgements were tested as measures of secondary school quality in multilevel models that controlled for background and family measures:

- How effective, efficient and inclusive is the provision of education, integrated care and any extended services in meeting the needs of learners?
- How well does the school work in partnership with others to promote learners' well-being?
- The effectiveness of the school's self-evaluation.
- The capacity to make any necessary improvements.
- Effective steps have been taken to promote improvement since the last inspection?
- How well do learners achieve?
- The standards reached by learners.
- How well learners make progress, taking account of any significant variations between groups of learners?
- How well learners with learning difficulties and disabilities make progress?
- The extent of learners' spiritual, moral, social and cultural development.
- The behaviour of learners.
- The attendance of learners.
- How well learners enjoy their education?
- The extent to which learners adopt safe practices.
- The extent to which learners adopt healthy lifestyles.
- The extent to which learners make a positive contribution to the community.
- How well learners develop workplace and other skills that will contribute to their future economic well-being?
- How good is the overall personal development and well-being of the learners?
- How effective are teaching and learning in meeting the full range of learners' needs?
- How well do the curriculum and other activities meet the range of needs and interests of learners?
- How well are learners cared for, guided and supported?

Appendix 10: Implications of the Abolition of National Tests at KS3 and the Strategy of Using Multiple Imputation for the Analysis of EPPSE Students' Academic outcomes in Year 9

10.1 Abolition of KS3 Tests

The Key Stage 3 National Assessment NPD dataset provides valuable measures of academic outcomes for students who are part of the EPPSE study. It has enabled analyses of both attainment and progress to be conducted in comparison to earlier KS data (KS1 and KS2). However, earlier analyses at KS1 and KS2 used test scores data rather than rely solely on TA levels³⁴.

In October 2008, it was announced that the requirement for schools to carry out KS3 tests would cease. Teacher Assessment would still be a requirement for students and test papers would still be available for schools to use, but here was no obligation on schools to conduct the tests or to report on results if there were undertaken.

This posed a challenge for the EPPSE team. KS3 test data was only available for the first two of the four EPPSE cohorts (a potential loss of 57% (N=1599) of the data on our main academic outcomes).

Options for analysis of KS3 Attainment data

The options for analysis following abolition of the tests were:

- a) Use National Assessment test data for the analysis of academic outcomes in Year 9, either i) just using actual scores for cohorts 1 and 2 where available or ii) using all four cohorts but reporting results based on the imputation of the large missing set of test data;
- b) Use Teacher Assessment (TA) data as outcomes for all four cohorts, which covered around 90% (N=2643 out of 2812³⁵) of the EPPSE sample. This would involve presenting results on TA outcomes where the number of cases that required TA levels to be imputed was much lower than for test scores.

Following analysis of these options we decided to use Teacher Assessment for our main outcome measures.

Undertaking analysis using KS3 National Assessment test scores, but only for cohorts 1 and 2 would have produced potentially misleading results. Cohorts 3 and 4 are somewhat different in composition to cohorts 1 and 2 (for example, they have a higher proportion of students who had attended better quality pre-schools, have more disadvantaged children and include most of the children who had not attended pre-school at all – the home group).

It would have been possible to use multiple imputation for the missing KS3 National Assessment test scores based on prior outcomes and other data. However, as some test data were missing for cohorts 1 and 2 and all data were missing for cohorts 3 and 4 this would have resulted in imputed scores being used for more EPPSE students than the number of students who had valid KS3 test

³⁴ Although we have analysed raw differences in results using TA levels and test scores for younger ages in KS1 and KS2 (Sammons et al., 2012).

³⁵ This represents the 'active sample'. However, in this report we used a slightly larger sample – the 'original sample' – (N=3002). Please see section 10.2.2 for details on obtaining this sample. The percentage of the TA data available for this sample was 86% (2574 out of 3002).

data. This was not considered to be the most appropriate option given the availability of valid TA levels for larger number of students in KS3 and the fact that using test scores with substantial amount of imputed data could be seen as less reliable.

Teacher Assessment data, on the other hand, were available for all four cohorts, with less than 15% missing. Imputing the missing data was considered to be the best option and would be less likely to see challenges to the analysis on methodological grounds. This decision was taken despite acknowledging some disadvantages in using teacher assessment (rather than test) data. Teacher assessment *levels* are not as highly differentiated as actual KS *point scores* and therefore offer much less sensitivity to variations in the effect of factors of interest. Teacher assessment data have also been found to increase the apparent achievement gap at age 14 for gender and for some measures of social disadvantage (possibly reflecting bias or perceptual influences on the professional judgements of teachers – see Sammons et al., 2009). The recent report by Lord Bew on the use of TA at KS2 has given attention to some of the problems of unreliability and bias in TA levels (Bew, 2011).

We considered that it was necessary to use all four cohorts in the KS3 analysis as this ensured that the pre-school experiences and the experiences of children from disadvantaged backgrounds were included in the analyses.

This technical report shows the results of the analyses based only on the original data (i.e., no missing data were imputed) and compared these to the resulted equivalent analyses based on the imputed datasets. It should be noted that the imputed results reported focus only on TA outcomes not the test scores.

10.2. The multiple imputation of background factors

The technical procedure for multiple imputation of missing data was conducted *simultaneously* for **all** variables (**background** and **outcome** measures) (see 10.2.2 for more details).

This approach to dealing with missing background data is increasingly advocated in major longitudinal studies (Little & Rubin, 1987; Rubin, 1987). It enhances the rigour and confidence which can be placed in results by maximising sample size, an important issue in longitudinal research, where sample attrition increases over time.

Overall, based on multiple testing and comparisons, we are confident that analyses conducted on the multiple imputation dataset led to very similar patterns of results to the ones obtained on the original data.

10.2.1 Testing of multiple imputation models

We evaluated different multiple imputation models, then applied the most robust to the EPPSE data.

As a first step (and as an internal exercise) we tested the technical performances of various multiple imputation procedures in relation to an original complete-case dataset. On the complete-case dataset, we randomly deleted values and imputed these deleted values using the following software and packages:

- STATA: contributed package *ICE*
- STATA: *MI* impute
- R: Package *MICE*
- R: Package *mi*
- R: Package *Amelia II*
- SAS: Standard *PROC MI* Procedure

The same growth curve model was tested on the original complete-case dataset and on the datasets created after multiple imputation. The estimates, standard errors and random-effects parameters obtained on the original complete-case dataset and the various resulting datasets were compared. Additionally, diagnostic plots that assessed the convergence of the imputation models were inspected. Comparing the results on imputed data with the results on a complete-case dataset was an important strategy to check how close the imputed values were to the 'real' values where these were already known.

Based on these comparisons and inspections, we concluded that the closest results to the original complete-case dataset were obtained on the datasets that were multiple imputed with the ICE (STATA) and Amelia II (R) procedures.

Following this decision, the original datasets were imputed using these two alternative approaches and more comparisons were conducted. This time, comparisons were made on the results of the multilevel models relevant to the EPPSE academic and social-behavioural outcomes. For the academic outcomes, the school variance, residual variance and the intra-school correlation (ICC) obtained on the dataset imputed with ICE (STATA) were found to be somewhat closer to the same parameters obtained on the original data than the parameters obtained on the dataset imputed with Amelia II (R).

After consideration of the various results, the ICE procedure was selected for the multiple imputations to be used in the analyses of students' KS3 academic outcomes and the results focused on the TA outcomes.

10.2.2 The multiple imputation strategy

We started with the original sample (N=3172) and selected only the cases for students who had academic outcomes for both English and maths for three or more time points. For Year 9, having either a test score or a TA was considered a valid data point. In addition, cases were only included if they did not have missing data on more than five out of a larger set of student and family background variables. The final sample size included N=3002 students.

The multiple imputation procedure replaces missing values for the specified variables with a set of possible values (where the number of values equals the number of the imputations). The missing values for any variable are predicted using existing values from other variables. Thus, if we specify 10 imputations, each missing value will be replaced by 10 possible values and the results reported are based on the average of the estimates across these sets of analyses on the 10 imputed datasets. This provides greater stability and reliability of findings.

The following variables were entered in the imputation model: birth weight, number of siblings, behavioural, developmental and health problems, mother's and father's qualification level, family SES, family salary, mother's and father's age, mother's and father's employment, marital status, Early Years HLE, KS1 and KS2 HLE factors, academic outcomes from baseline to Year 9 (test scores but for KS2 and KS3 also TA levels), neighbourhood safety, Year 6 and Year 9 FSM, and Year 9 SEN. The exact percentages of missing data on each of the relevant variables are shown in Tables 1.5 and 1.6 from Section 1. They range from 1.3% to 25.5%.

In addition, items from the "All about me" and "All about me in school" questionnaires were also included into the imputation model (i.e., revision classes for SATs, time spent on homework, time spent on watching TV/DVDs/Videos, time spent on household work, etc.). Finally, we included in the imputation model the factor scores related to teaching and school processes (i.e., 'emphasis on learning', 'behaviour climate', 'teacher discipline' etc.), and also students' self-perceptions ('academic self-concept', 'enjoyment of school', 'anxiety').

As noted earlier, the multiple imputation procedure imputes data simultaneously for **all** the specified variables in the imputation model (thus, for example, background characteristics and academic

outcomes are imputed at the same time), creating 10 stacked datasets that have complete data for the imputed variables.

The multilevel models were tested on all 10 datasets (as STATA has the capacity to recognise a multiple imputed dataset) and the results were combined following Rubin's rule and presented as an overall model.

10.2.3 Comparison of Original and Imputed data

This technical report provides tables of results throughout providing the details of both the original (N=3002 with the level of missing data being variable: 14% for TA levels, 25.5% for father's qualification etc.) and the imputed datasets (N=3002 which is the pooled sample of the 10 imputed data sets with no missing values for the variables listed above). The results are broadly consistent across both sets of analysis in terms of size and direction of association which provides confidence in the findings.

Multiple imputation is not a perfect procedure and moreover, because of the non-random nature of the missing data in the original dataset (a problem in nearly all social and educational research as data are very rarely missing at random), we expected that in some cases the estimates would differ. This would most likely be for variables with high levels of missing values and/or where missing values reflected special characteristics (e.g. where father's qualification or family SES data is missing because the father was absent from the family from an early age rather than present but not providing data).

When exploring the differences between results obtained on the original data and imputed data, the focus was on the size of the absolute difference rather than on the statistical significance. The cut off point for the size of this difference in the effect sizes ($ES_{orig} - ES_{imp}$) was chosen to be 0.15. Thus, in the cases where the pattern of effect sizes was broadly similar and the differences within the cut off point, the slight differences in statistical significance were not given an undue weight (since any choice of significance level is, to some extent, arbitrary). Differences in the statistical significance between the original and imputed data could be due to the sample size (the effect size not significant on the original data but reaches significance on the (larger) imputed dataset) or to the way the missing data are (re)distributed in the imputation model (this is probably the case for the variables with large proportions of missing values and where missing values are not missing at random).

The differences in effect sizes (in absolute terms) obtained in the contextualised models on the original and imputed data sets varied from 0 to 0.35. Considering the simple contextualised (CM) and the value added contextualised models (CVAM), we identified the following variables for which the differences in effect sizes between the two data sets were higher than 0.15: birth weight, family SES, salary, father's qualification, Year 6 test scores and ethnicity. However, these were exceptions that did not affect the robustness of the overall results. They make very little difference to the overall model as it can be seen from the comparisons of model statistics such as total variance accounted for and relevant SE for different predictors. In the case of larger differences (0.17-0.22) for the father's qualification measure, the imputed results are likely to be more stable. This could be because of the inclusion of students with absent father into the missing category (i.e., whose qualifications were not known) that can be, however, robustly imputed from other known measures (e.g., mother's qualification, income, family SES etc.).

In the contextualised and value added models that also tested the impact of secondary school quality (measured by Ofsted judgements related to the 'quality of student's learning' and 'attendance of learners') on the academic attainment, some of the effect sizes for the 'missing' category on the two data sets were either in opposite direction (although none of them significant) or the differences between them were higher than 0.15 (see Table A.10.1 and Table A.10.2 below). The 'missing' category for both data sets was retained as we deemed it inappropriate to impute missing data for the Ofsted secondary school measures because, unlike students' measures, there were fewer

variables that might help predict Ofsted results (this missing category would include private schools but also others that had not been inspected within the relevant time frame).

Table A.10.1: Contextualised Models: Selected Differences in ES between Original and Imputed Data Above the 0.15 Cut Off

Background Variables					
Year 9 English TA levels		Year 9 Maths TA levels		Year 9 Science TA levels	
Variable	Difference $ ES_{orig}-ES_{imp} $	Variable	Difference $ ES_{orig}-ES_{imp} $	Variable	Difference $ ES_{orig}-ES_{imp} $
Birth weight- Very low (ref. Normal)	0.16*	Birth weight- Very low (ref. Normal)	0.19*		
		Family SES- Unskilled (ref. Highest)	0.17*		
		Father's Qualification- Degree (ref. None)	0.17*	Father's Qualification- Degree (ref. None)	0.22*
Secondary School Variables					
Attendance of Learners- Missing (ref. Inadequate)	0.35 [†]	Attendance of Learners- Missing (ref. Inadequate)	0.24*	Attendance of Learners- Missing (ref. Inadequate)	0.29 [†]
		Quality of Student's Learning- Missing (ref. Inadequate)	0.27 [†]		

*ES significant on both the original and imputed data

[†]ES significant on original data only

Table A.10.2: Contextualised Value Added Models: Selected Differences in ES between Original and Imputed Data Above the 0.15 Cut Off

Background Variables					
Year 9 English TA levels		Year 9 Maths TA levels		Year 9 Science TA levels	
Variable	Difference $ ES_{orig}-ES_{imp} $	Variable	Difference $ ES_{orig}-ES_{imp} $	Variable	Difference $ ES_{orig}-ES_{imp} $
Salary- >67500 (ref. No Salary)	0.28 [†]	Year 6 Test Scores [^]	0.20*	Father's Qualification - Academic Age 18 (ref. None)	0.20 [†]
		Ethnicity- Bangladeshi (ref. White UK)	0.26*	Father's Qualification- Degree (ref. None)	0.22*
Secondary School Variables					
Attendance of Learners (ref. Inadequate)	0.30 [†]	Attendance of Learners (ref. Inadequate)	0.33 [†]		
		Quality of Student's Learning (ref. Inadequate)	0.33 [†]		

*ES significant on both the original and imputed data

†ES significant on original data only

^Note that the ES for prior Maths Scores is very large (2.99 vs. 2.79) in both analyses and this difference is relatively modest

Summary

A limitation of the present study is the fact that our analyses that predicted TA levels as the outcome (dependent variable) do not allow us to address potential bias in TA judgments regarding different student groups. However, these were explored in a previous report where we compared TA levels to test scores for cohorts 1 and 2 (Sammons et al., 2009).

All social science and educational research is affected by the problem of missing data. The use of valid cases ignores or masks the problem, but also entails the potential for bias because data is very rarely missing at random. In our EPPSE analyses, we have sought to identify and address the issue of missing data explicitly to increase the rigor of the research and the findings.

Overall, based on multiple testing and comparisons, we are confident that analyses conducted on the multiple imputation dataset led to very similar patterns of results to the ones obtained on the original data. By presenting the results based on both sets of data, it is possible to show how the patterns of results are consistent across both sets of analyses. This enabled us to capitalise on the larger sample size in the imputed data that enhances our ability to identify statistically significant effects for the predictors.

Glossary of terms

Academic self-concept EPPSE derived two measures of Academic self-concept from Year 9 student questionnaire data:

- 1) 'Academic self-concept for English'
- 2) 'Academic self-concept for maths'

Both of the above measures are based on items taken from existing well established 'academic self-concept' scales (Marsh, 1990a; 1990b; Marsh & Hau, 2003; Marsh & Craven, 2006).

Age standardised scores Assessment scores that have been adjusted to take account of the pupil's age at testing. This enables a comparison to be made between the cognitive outcome of an individual pupil, and the relative achievement of a representative sample of pupils in the same age group throughout the country or, in this case, the relative achievement of the EPPE sample.

Anxiety A factor derived from Year 9 student questionnaire items that reflect the degree to which the students feel unhappy, worried, nervous, fearful in new situations, or suffer from minor ailments.

'at risk' The term 'at risk' is a complex one which will differ depending on the particular criteria used. For instance, the definition of possible cognitive 'at risk' status used in the ETYSEN study (see Taggart et al., 2006), based on children's cognitive attainment at entry to pre-school, was a score of one standard deviation (sd) below the mean (in standardised assessments) in relation to national norms (at risk). In the more recent EPPSE case studies, there are various definitions of risk and resilience (see Siraj-Blatchford et al., 2011).

Anti-social behaviour A social-behavioural construct identified from teachers' ratings about EPPSE students, collected through a pupil profile based on Goodman's (1997) Strength and Difficulties questionnaire. Five items formed the factor 'anti-social' behaviour e.g. Steals from home, school or elsewhere.

British Ability Scales (BAS) This is a battery of assessments specially developed by NFER-Nelson to assess very young pupils' abilities. The assessments used at entry to the EPPE study and at entry to reception were:

Block building - Visual-perceptual matching, especially in spatial orientation (only entry to study)

Naming Vocabulary – Expressive language and knowledge of names

Pattern construction – Non-verbal reasoning and spatial visualisation (only entry to reception)

Picture Similarities – Non-verbal reasoning

Early number concepts – Knowledge of, and problem solving using pre-numerical and numerical concepts (only entry to reception)

Copying – Visual-perceptual matching and fine-motor co-ordination. Used specifically for pupils without English

Verbal comprehension – Receptive language, understanding of oral instructions involving basic language concepts.

Birth weight In the EPPSE research, babies born weighing 2500 grams (5lbs 8oz) or less are defined as below normal birth weight; foetal infant classification is below 1000 grams, very low birth weight is classified as 1001-1005 grams and low birth weight is classified as 1501-2500 grams (Scott and Carran, 1989). When EPPSE uses this measure in analyses, the categories foetal infant (<1000g) and very low birth weight (1001-1005g) are often collapsed into one category due to small numbers in the former group.

Centre/School level variance The proportion of variance in a particular child/student outcome measure (i.e. Year 9 English Teacher Assessment level at the end of Key Stage 3 in secondary school) attributable to differences between individual centres/schools rather than differences between individual children/students.

Citizenship values A factor derived from Year 9 student questionnaire items that relate to how important students feel certain behaviours are such as strong people not picking on weak people,

respecting rules and laws, controlling your temper, respecting other's views, and sorting out disagreements without fighting.

Comparative Fit Index (CFI) The CFI is an index of a statistical model fit that takes into account sample size. Values close to 0.95 indicate good fit (Hu & Bentler, 1999).

Compositional effects The influence of a student's peer group on that particular student's individual outcomes.. For example, the influence of attending a school where a high percentage of students are in receipt of Free School Meals (FSM) or come from disadvantaged backgrounds. This influence is irrespective of the characteristics (FSM status) of the individual student in question. For further details see Harker (2001).

Confidence intervals (at 95 or 99%) A range of values which can be expected to include the 'true' value in 95 or 99 out of 100 samples (i.e. if the calculation was repeated using 100 random samples).

Contextualised models Cross-sectional multilevel models exploring individuals' outcomes, while controlling for individual, family and home learning environment characteristics (but not prior attainment).

Controlling for Several variables may influence an outcome and these variables may themselves be associated. Multilevel statistical analyses can calculate the influence of one variable upon an outcome having allowed for the effects of other variables. When this is done the net effect of a variable upon an outcome controlling for other variables can be established.

Correlation A correlation is a measure of statistical association that ranges from + 1 to -1.

Cronbach's alpha (α) A measurement of the internal reliability (or consistency) of the items on a test or questionnaire that ranges between 0 and 1 showing the extent to which the items are measuring the same thing (Reber, 1995). A value greater than 0.7 ($\alpha < 0.7$) suggests that the items consistently reflect the construct that is being measured.

CVA (Contextualised Value Added) Measures of secondary school academic effectiveness derived from KS2-KS4 contextual value added (CVA) indicators produced by the Department for Education (DfE). At the pupil level, the CVA score was calculated as the difference between predicted attainment (i.e., the average attainment achieved by similar pupils) and real attainment in KS4. The predicted attainment was obtained by using multilevel modelling controlling for pupils' prior attainment and adjusting for their background characteristics (i.e., gender, age, ethnicity, SEN, FSM, mobility etc.). For each school, all individual pupil scores were averaged and adjusted for the proportion of pupils attending the school in a specific year. This final averaged score represents the school level CVA and it is presented as a number based around 1000 (for more technical details see http://www.education.gov.uk/performance/tables/schools_08/documents.shtml).

Dispositions An overarching term used to refer to factors such as '*enjoyment of school*', '*academic self concept (English and maths)*', '*popularity*', '*citizenship values*' and '*anxiety*'. The EPPSE study derived these factors from questionnaires completed by students in Year 9 called 'All about Me' and 'All about Me in school'.

ECERS-R and ECERS-E The American Early Childhood Environment Rating Scale (ECERS-R) (Harms et al., 1998) is based on child centred pedagogy and also assesses resources for indoor and outdoor play. The English rating scale (ECERS-E) (Sylva et al., 2003; 2006) was intended as a supplement to the ECERS-R and was developed specially for the EPPE study to reflect the Desirable Learning Outcomes (which have since been replaced by the Early Learning Goals, the Curriculum Guidance for the Foundation Stage, and the Early Years Foundation Stage). For more information see Sylva et al., (2010).

Educational effectiveness Research design which seeks to explore the effectiveness of educational institutions in promoting a range of child/student outcomes (often academic measures) while controlling for the influence of intake differences in child/student characteristics.

Effect sizes (ES) Effect sizes (ES) provide a measure of the strength of the relationships between different predictors and the outcomes under study. For further information see Elliot & Sammons (2004).

Emphasis on learning A factor derived from Year 9 student questionnaire items that relate to teacher expectations, emphasis on understanding something not just memorising it, teachers believing that it is okay for students to make mistakes as long as they learn from them, students wanting to do well in exams, and lessons being challenging.

Enjoyment of school A factor derived from Year 9 student questionnaire items that reflect the degree to which students reported they like lessons and being at school, like answering questions in class, but also how much the student experiences boredom in lessons or feels school is a waste of time.

Factor Analysis (FA) An umbrella term covering a number of statistical procedures that are used to identify a smaller number of factors or dimensions from a larger set of independent variables or items (Reber, 1995). At KS3 EPPSE used:

- Exploratory FA – a type of analyses where no prior (theoretical) knowledge is imposed on the way the items cluster/load.
- Principal Components Analysis (PCA) – a procedure that converts a set of observations of possibly correlated items into a set of values of uncorrelated items called principal components.
- Confirmatory FA – type of factor analyses used where the measure of a factor/construct are tested against a prior (theoretical) knowledge.

Family characteristics Examples of family characteristics are mother's highest qualification level, father's highest qualification level and family socio-economic status (SES).

Free school meals (FSM) An indicator of family poverty.

General Cognitive Ability (GCA) A measure of pupils' overall cognitive ability, incorporating non-verbal and verbal BAS sub-scales.

Growth Curve Modelling "In brief, the objective of growth curve modeling¹ is to describe a set of time-ordered, within-person observations using only a few parameters. For example, the intra-individual change over time, or within-person learning, that occurs with practice might be described parsimoniously by two parameters, one indicating an individual's initial level of ability (e.g., intercept), and another indicating linear rate of increase or decline in performance across multiple occasions of measurement (e.g., linear slope)...Growth curve modeling methods also allow us to describe and test hypotheses about individual differences in intra-individual change. By allowing the parameters used to describe intra-individual change to vary between individuals we can also model and examine how (and potentially why) individuals differ in their initial levels of performance (intercept), rates of improvement or decline over time (linear slope), asymptotic levels of performance, etc. Examining how the inter-individual differences in particular aspects of intra-individual change captured by each parameter relate to other inter-individual differences (e.g., covariates such as trait personality) brings us one step closer to understanding how and why individuals follow different paths of development" (Ram & Grimm, 2007; p. 303).

Headteacher qualities A factor derived from Year 9 student questionnaire items that reflect the headteacher making sure that students behave well, their presence around the school and interest in how much students learn.

Hierarchical nature of the data Data that clusters into pre-defined sub-groups or levels within a system (i.e. students, schools, local authorities).

Home learning environment (HLE) characteristics Measures derived from reports from parents (at interview or using parent questionnaires) about what children do at home (with/independent of their parents). There are several HLE measures: early years HLE, KS1 HLE, KS2 HLE (please see Appendix 5 for further details).

Hyperactivity A social-behavioural construct identified from teachers' ratings about EPPSE students, collected through a pupil profile based on Goodman's (1997) Strength and Difficulties questionnaire. Several items formed the factor 'hyperactivity' e.g. Restless, overactive, cannot stay still for long.

Income Deprivation Affecting Children Index (IDACI) The IDACI represents the percentage of children in each SOA that live in families that are income deprived. For further details see Noble et al., 2008.

Index of Multiple Deprivation (IMD) The IMD is a measure of a range of characteristics evident in a neighbourhood. For further details see Noble et al., 2004; 2008.

Internal Reliability/Consistency The degree to which the various parts of a test (items) or other instrument (e.g. questionnaire) measure the same variables/construct (Reber, 1995). An example measure would be **Cronbach's alpha** (see earlier).

Intra-centre/school correlation The intra-centre/school correlation measures the extent to which the outcomes from children/students in the same centre/school resemble each other as compared with those from children/students at different centres/schools. The intra-centre/school correlation provides an indication of the extent to which unexplained variance in children's/students' progress (i.e. that not accounted for by prior attainment) may be attributed to differences between centres/schools. This gives an indication of possible variation in pre-school centre/school effectiveness.

Key Stage (KS) The English education system splits students into age phases known as Key Stages as follows: KS1 (age 5-7), KS2 (8-11), KS3 (12-14), KS4 (14-16).

Mean average A measure of central tendency that is calculated by summing a set of values (or scores) and then dividing by the number of values or scores (Reber, 1995).

Multilevel modelling A methodology that allows data to be examined simultaneously at different levels within a system (i.e. children/students, pre-school centres/schools, local authorities), essentially a generalisation of multiple regression.

Multiple Disadvantage Index of Risk This measure was developed as part of the Early Years Transition & Special Educational Needs (EYTSN) Project, which focuses on the identification of children 'at risk' of SEN (see Sammons et al., 2004d). An index was created based on 10 indicators in total: three child variables, six parent variables, and one related to the Early years Home Learning Environment (HLE).

Child variables

- First language: English as an additional language (EAL)
- Large family: 3 or more siblings
- Pre-maturity / low birth weight

Parent/HLE variables

- Mother's highest qualification level: no qualifications
- Social class of father's occupation: Semi-skilled, unskilled, never worked, absent father
- Father not employed
- Young Mother (Age 13-17 at birth of EPPE child)
- Lone parent
- Mother not working / unemployed
- Low Early years Home Learning Environment (HLE)

For further details see Sammons et al., 2002.

Multiple imputation A statistical procedure that replaces missing value with a set of predicted values (Little & Rubin, 1987). This procedure generates several imputed data sets, which are then analysed and the results combined according to Rubin's Rule (Little & Rubin, 1987).

Multiple regression A method of predicting outcome scores on the basis of the statistical relationship between observed outcome scores and one or more predictor variables.

National Assessment Levels The table below shows the levels that could be achieved by a student at different ages in their National Assessments tests / can be awarded to a student for their Teacher Assessment (TA).

Outcome	Key Stage 1 (KS1), Age 7	Key Stage 2 (KS2), Age 11	Key Stage 2 (KS3), Age 14
Reading/English Levels	Working towards level 1 Level 1 Level 2 – Expected Level Level 3 Level 4	Level 1 Level 2 Level 3 Level 4 – Expected Level Level 5 Level 6	Level 1 Level 2 Level 3 Level 4 Level 5 – Expected Level Level 6 Level 7 Level 8
Maths Levels	Working towards level 1 Level 1 Level 2 – Expected Level Level 3 Level 4	Level 1 Level 2 Level 3 Level 4 – Expected Level Level 5 Level 6	Level 1 Level 2 Level 3 Level 4 Level 5 – Expected Level Level 6 Level 7 Level 8
Science Levels	Working towards level 1 Level 1 Level 2 – Expected Level Level 3 Level 4	Level 1 Level 2 Level 3 Level 4 – Expected Level Level 5 Level 6	Level 1 Level 2 Level 3 Level 4 Level 5 – Expected Level Level 6 Level 7 Level 8

Net effect The unique contribution of a particular variable upon an outcome while other variables are controlled.

Ofsted The Office for Standards in Education, Children's Services and Skills (Ofsted) inspect and regulate services that care for children and young people, and those providing education and skills for learners of all ages. See Matthews & Sammons (2004), and the Ofsted website (<http://www.ofsted.gov.uk/content>) for further details.

Pedagogical strategies Strategies used by an educator to support learning. These include the face to face interactions with students, the organisation of resources and the assessment practices.

(Poor) behaviour climate A factor derived from Year 9 student questionnaire items that relate to the general behaviour climate in the EPPSE student's school; students being given a hard time by others if they work hard, level of compliance with school rules, fighting and weapons being brought into school, and whether most students want to leave the school as soon as they can.

Popularity A factor derived from Year 9 student questionnaire items that relate to how popular students feel they are with other teenagers and how many friends they have.

Pre-reading attainment Composite formed by adding together the scores for phonological awareness (rhyme and alliteration) and letter recognition.

Pre-school effectiveness Measures of the effectiveness of pre-schools were derived from Value Added (VA) models of the sample's actual progress during pre-school, controlling for prior attainment and children's background characteristics (Sammons et al., 2004b).

Primary school effectiveness Primary school academic effectiveness scores were obtained from National Assessment data for several cohorts across all primary schools in England. Value-added scores were calculated across the years 2002-4, for each primary school in England and then extracted for schools attended by the EPPE sample (Melhuish et al., 2006a; 2006b).

Prior attainment Measures which describe a participant's achievement at the beginning of the phase or period under investigation (i.e. taken on entry to the study or school, or for Year 9 analyses, outcomes from Year 6).

Pro-social Behaviour A social-behavioural construct identified from teachers' ratings about EPPSE students, collected through a pupil profile based on Goodman's (1997) Strength and Difficulties questionnaire. Several items formed the factor 'pro-social' behaviour e.g. Considerate of other people's feelings.

Pupil Profile An instrument containing Goodman's (1997) Strength and Difficulties questionnaire plus some additional items used to collect information about EPPSE student's social behaviour. It is completed by a teacher who knows the EPPSE student well.

Quality of pre-school Measures of pre-school centre quality were collected through observational assessments (ECERS-R, ECERS-E) completed by trained researchers. For further information see **ECERS** and Sylva et al. 2010.

Quality of secondary schools Secondary school quality was derived from measures taken from Ofsted inspection judgements. See **Ofsted** for further details.

Quality of teaching Measures from Year 5 classroom observations using the IEO (Stipek) and COS-5 (Pianta) instruments. For further information see Sammons et al. (2006a; 2006b).

Root Mean Square Error of Approximation (RMSEA) The RMSEA is an index measure of model; values less than 0.06 are an indication of a good fit.

Sampling profile/procedures The EPPSE sample was constructed of: Five regions (six Local authorities) randomly selected around the country, but being representative of urban, rural, inner city areas. Pre-schools from each of the 6 main types of target provision (nursery classes, nursery schools, local authority day nurseries, private day nurseries, play groups and integrated centres) randomly selected across the region.

School environment A factor derived from Year 9 student questionnaire items that relate to how EPPSE students view their school in terms of the physical space (the attractiveness of buildings, the decorative state of the classrooms, the condition of the toilets), as well as its reputation as a good school and how well organised it is.

School/learning resources A factor derived from Year 9 student questionnaire items that relate to practical resources for learning at the EPPSE student's school; amount of computers and getting enough time on them in lessons, and the quality of science labs and the school library.

School level variation School level variance here refers to the percentage of variation in students' outcomes that can be attributed to differences between schools.

Secondary school effectiveness Secondary school academic effectiveness scores were obtained from the Department for Education (DfE). The measure of academic effectiveness is represented by the average KS2 to KS4 contextual value added (CVA) school level scores over 4 years (2006-2009) when EPPSE students were in secondary school. See '**CVA**' as this is the same measure.

Self-regulation A social-behavioural construct identified from teachers' ratings about EPPSE students, collected through a pupil profile based on Goodman's (1997) Strength and Difficulties questionnaire. Several items formed the factor 'self-regulation' e.g. Likes to work things out for self; seeks help rarely.

Significance level Criteria for judging whether differences in scores between groups of children/students or centres/schools might have arisen by chance. The most common criteria is the 95% level ($p < 0.05$), which can be expected to include the 'true' value in 95 out of 100 samples (i.e. the probability being one in twenty that a difference might have arisen by chance).

Social-behavioural development A student's ability to 'socialise' with other adults and pupils and their general behaviour to others. EPPSE uses this overarching name to refer to a range of social-behavioural outcome measures. At age 14, two of these outcomes refer to positive outcomes ('self-regulation' and 'pro-social' behaviour) and two refer to negative outcomes ('hyperactivity' and 'anti-social' behaviour).

Socio-economic status (SES) Occupational information was collected by means of a parental interview/questionnaire at different time points. The Office of Population Census and Surveys OPCS (1995) Classification of Occupations was used to classify mothers and fathers current employment into one of 8 groups: professional I, other professional non manual II, skilled non manual III, skilled manual III, semi-skilled manual IV, unskilled manual V, never worked and no response. Family SES was obtained by assigning the SES classification based on the parent with the highest occupational status.

Standard deviation (sd) A measure of the spread around the mean in a distribution of numerical scores. In a normal distribution, 68% of cases fall within one standard deviation of the mean and 95% of cases fall within two standard deviations.

Structural equation modelling (SEM) is an umbrella term for statistical modelling techniques which allow for testing causal processes and structural relationships (Byrne, 2010).

Student background characteristics Student background characteristics include age, birth weight, gender, and ethnicity.

Target centre A total of 141 pre-school centres were recruited to the EPPSE research covering 6 types of provision - **Sampling profile/procedures**. The sample of students was drawn from these target centres.

Teacher Assessment (TA) These assessments made by teachers provide measures of students' educational outcomes for English, maths and science in Year 9 (age 14) in the form of National curriculum levels.

Teacher discipline A factor derived from Year 9 student questionnaire items that relate to the level of teacher control during lessons, in terms of behaviour, noise, rule breaking and teachers being bothered if students turn up late.

Teacher support A factor derived from Year 9 student questionnaire items that relate to support given by teachers in terms of helping students, giving them feedback, making them feel confident about their work, rewarding them for good behaviour, being available to talk privately, and marking and returning homework.

Term of birth Using EPPSE student's dates of birth, the EPPSE sample were categorised into three 'term of birth' categories: Autumn born (September to December); Spring born (January to April); Summer born (May to August).

Total BAS score By combining 4 of the BAS sub-scales (2 verbal and 2 non-verbal) a General Cognitive Ability score or Total BAS score at entry to the study can be computed. This is a measure of overall cognitive ability.

Value added models Longitudinal multilevel models exploring individuals' progress over time, controlling for prior attainment as well as significant individual, family and home learning environment characteristics.

Value added residuals (pre-school effectiveness) Differences between predicted and actual results for pre-school centres (where predicted results are calculated using value added models). See **Pre-school effectiveness** for further information.

Value added residuals (primary school academic effectiveness) Differences between predicted and actual results for primary schools measuring pupil progress across KS1 – KS2. For further information see **Primary school effectiveness** and Melhuish et al. (2006a; 2006b).

Valuing pupils A factor derived from Year 9 pupil questionnaire items that relate to whether the school values students' views, teachers listen to students views, are respectful and friendly to students, teachers are unpleasant to students if they make mistakes.

Views of school An overarching term used to refer to factors such as 'teacher support', 'school environment', 'valuing students', 'headteacher qualities', 'poor behaviour climate', 'emphasis on learning', 'teacher discipline', and 'school/learning resources'. The EPPSE study derived these factors from the questionnaire completed by students in Year 9 called 'All about me in school'.
